Abstract: To investigate the correlation between computed tomography (CT) features and glycosylated hemoglobin (HbA1c) levels in patients with type 2 diabetes mellitus (T2DM) complicated with primary pulmonary tuberculosis (PTB). One hundred and eighty untreated PTB patients complicated with T2DM were selected. Based on the HbA1c level, the patients were divided into three groups: HbA1c level <7% (Group I: 32 patients), 7%–9% (Group II: 48 patients), and >9% (Group III: 100 patients). The changes of CT manifestations and HbA1c were analyzed after TB and T2DM treatment. In the three groups, the detection rate of large segmented leafy shadow was 50%, 56.2%, and 87%; the air bronchogram sign detection rate was 40.6%, 47.9%, and 77%; the discovery rate of mouth-eaten cavity was 31.2%, 45.8%, and 65%; thick wall cavity detection rate was 25%, 31.2%, and 52%; the rate of multiple cavities was 34.3%, 50%, and 73%; and bronchial TB was found in 33.3%, 21.8%, and 46%, respectively. The detection rates of lesions in Group III were significantly higher than in Group II and Group I ($p < 0.05$), and this increase was significant ($p < 0.05$). After treatment, the HbA1c level reached control target (<7%) among all three groups and CT absorption improvement rates were 100%, 72.9%, and 56% respectively. The therapeutic efficacy of group I was better than group II ($p < 0.01$), and the treatment efficacy of group II was better than group III ($p < 0.05$). CT manifestations of T2DM complicated with PTB were closely related to HbA1c level. The effect is better when HbA1c level <7%. HbA1c level effectively reflects the severity and therapeutic effect to a certain extent. CT scan can provide some important information for clinical imaging. The above two examinations can guide clinicians to formulate the appropriate diagnosis and treatment in a timely manner.

Introduction

Primary pulmonary tuberculosis (PTB) is a serious threat to human health. According to the "Global Tuberculosis Report 2016" of the World Health Organization, in 2015, there were an estimated 10.4 million new (incident) TB cases worldwide.¹ The rapid increase in TB morbidity where diabetes mellitus (DM) is epidemic indicates that DM may be a risk factor.² Recent studies have also shown that TB in patients with DM compared to those without DM displays a different clinical manifestation and clinical outcome.^{3,4} However, there are still some studies showing that DM does not affect TB.^{5–9} Although the association between TB and DM has been described and researched for centuries, the correlation between computed tomography (CT) imaging features and glycosylated hemoglobin (HbA1c) levels in type 2 diabetic patients (T2DM) with PTB has not

been thoroughly studied. Song et al¹⁰ conducted a study to investigate the CT imaging features for T2DM patients with multidrug-resistant TB, (defined as TB strains resistant to at least isoniazid and rifampin). They found consolidation in or above multiple pulmonary segments with multiple mouth-eaten cavities and bronchial damage on CT images in T2DM patients with TB, suggesting the possibility of multidrug resistance. Also, Kim et al¹¹ aimed to assess CT features of PTB and TB pleurisy in DM patients and to evaluate the effect of duration of DM on CT imaging findings of PTB and TB pleurisy. The study from Kim suggested that involvement of all lobes, bilateral pulmonary involvement, and lymph node enlargement are significantly more common CT features in TB patients with DM than in those without DM. It is well known that TB and DM can be controlled, and the relationship between these two diseases is not particularly clear. Huang et al¹² evaluated the impact of glycemic status on CT findings of PTB in DM patients as well. They suggested that glycemic status influenced radiological manifestations of PTB with DM as there was an increased risk of atypical radiological presentations of PTB in DM patients. In order to reduce the risk of misdiagnosis due to atypical radiologic findings in TB DM patients, physicians should be alert enough to pay more attention to PTB patients with poor glycemic control.

This study analyzed the imaging and clinical features of 180 T2DM patients with PTB and without HIV infection or other pulmonary complications (chronic obstructive pulmonary diseases or any other lung diseases) from April 1, 2012 to March 31, 2015. This analysis investigated the correlation between CT imaging features and HbA1c levels in patients with T2DM complicated with PTB.

Patients and methods

Patients

This imaging study was conducted in the Huai'an Infectious Disease Hospital. From April 1, 2012 to March 31, 2015; 189 patients (aged 23–86 years) with the diagnosis of primary pulmonary TB complicated with T2DM were screened, and complete medical data were available for research review and analysis. All subjects in the study were HIV negative. This study was approved by the ethics committee of the Huai'an Infectious Disease Hospital; all methods were performed in accordance with the relevant guidelines and regulations, all patient data were analyzed for anonymity, and therefore, according to the ethics committee of the Huai'an Infectious Disease Hospital, no additional informed consent was required.

The clinical data of all patients included age, gender, smoking, alcohol abuse, the time interval, and HbA1c level at the first diagnosis of DM and TB. Inclusion criteria were

as follows: 1) fulfilling the criteria for clinical diagnosis of diabetes; 2) fulfilling at least one of the following four points for diagnosis of TB: 1) sputum smear and (or) sputum cultures positive, 2) bronchoscopy brush biopsy positive, 3) percutaneous lung biopsy or bronchoscopy confirmed pathologically, 4) typical TB clinical symptoms and chest CT manifestations, excluding other nontuberculous pulmonary disease, and anti-TB treatment is effective. Patients were excluded if they could not use first-line anti-TB drugs due to abnormal hepatic laboratory tests.

Based on the HbA1c level detection results and Chinese type 2 diabetes prevention and treatment guidelines (2013 version),¹³ all patients were divided into three groups: HbA1c level <7% is the group with good blood glucose control (Group I, n=32), HbA1c level from 7% to 9% is group in which blood glucose is generally well controlled (Group II, n=48), and HbA1c level >9% is group with poor control (Group III, n=100). Based on the presence of cough, sputum, hemoptysis, fever, symptom score, night sweats, and weight loss (one point per item), we define a higher symptom score when patients present with at least four of these symptoms.

CT image acquisition

All patients in our study underwent CT imaging scan when they were first diagnosed, and changes in CT manifestations and HbA1c level were analyzed after anti-TB treatment. The CT examination was performed with a Germany SIEMENS spirit spiral CT scanner. After patients inhale a deep breath, CT scan was started with the range from apex to both sides of the lower edge of the costophrenic angle. The conventional scan layer thickness is 6 mm, some cases underwent high-resolution CT scan, with a thickness of layer of 2 mm. The tube ball voltage was 130 kV and the tube ball current was 175–250 mA.

The primary outcome was differences in radiographic findings and final treatment outcomes. The CT images were recorded and examined by two TB experts and two radiologists blinded to status of diabetes control, and consensus was reached. The position, size, shape, cavity, calcification, bronchus, lymph nodes, and pleural effusion were observed and analyzed.

Statistical methods

Statistical analyses were performed using SPSS 21.0 (SPSS Inc., Chicago, IL, USA). Measurement data for variables with normal distributions (age, body mass index and HbA1c level) were compared using independent *t*-test, and those without normal distributions, such as the number of involved lobes, were compared using nonparametric tests. The count data were compared using a χ^2 test, and the ranked data were compared using a nonparametric rank sum test. The imaging risk factors related to DM TB were

analyzed using binary multivariate logistic regression analysis. $p < 0.05$ was considered as statistically significant.

Results

Characteristics of the clinical data for T2DM TB patients

Patient enrollment started on April 1, 2012, and a total of 180 TB patients were screened before March 31, 2015. Among 180 new PTB patients with T2DM, none were

excluded due to missing data or any other reason. And so, finally, 180 cases were included in our study. All 180 patients were diagnosed previously with T2DM during the workup of PTB. Based on the HbA1c level detection results and Chinese type 2 diabetes prevention and treatment guidelines (2013 version),¹³ all patients were divided into three groups: HbA1c level $< 7\%$ (Group I, $n=32$), HbA1c level from 7% to 9% (Group II, $n=48$), and HbA1c level $> 9\%$ (Group III, $n=100$) (Table 1).

Table 1 Characteristics of patients with PTB, according to diabetes control status

| Demographic characteristics | Group I N=32 | Group II N=48 | Group III N=100 | p-value |
|---------------------------------------------------------------|-----------------------------|-----------------------------|-------------------------------|----------|
| Age, years, mean \pm SD (range) | 58.0 \pm 14.0 (26–86) | 58.6 \pm 12.6 (24–84) | 58.6 \pm 13.3 (23–81) | > 0.05 |
| Gender, male | 23/32 (71.9) | 35/48 (72.9) | 75/100 (75) | > 0.05 |
| BMI, mean \pm SD (kg/m ²) | 21.9 \pm 2.5 | 20.3 \pm 3.0 | 21.1 \pm 1.9 | > 0.05 |
| Smokers vs nonsmokers | 19/32 (59.4) | 30/48 (62.5) | 63/100 (63) | > 0.05 |
| Alcohol abuse | 4/32 (12.5) | 6/48 (12.5) | 13/100 (13) | > 0.05 |
| Time interval between the first diagnosis of disease (months) | | | | |
| T2DM, mean \pm SD (range) | 88.75 \pm 73.37 (0.5–360) | 88.65 \pm 80.99 (0.4–350) | 88.43 \pm 73.67 (0.5–356) | > 0.05 |
| PTB, mean \pm SD (range) | 2.10 \pm 0.70 (0.5–3) | 1.90 \pm 0.70 (0.4–3) | 2.05 \pm 0.66 (0.5–3) | > 0.05 |
| Symptom | | | | |
| Cough | 25/32 (78.1) | 39/48 (81.3) | 84/100 (84) | < 0.05 |

Notes: Data are presented as the number (%) of subjects, unless otherwise indicated. Group I: HbA1c level $< 7\%$; Group II: HbA1c level from 7% to 9% ; Group III: HbA1c level $> 9\%$. * $p < 0.05$ compared with Group I, *** $p < 0.05$ compared with Group II.

Abbreviations: BMI, body mass index; T2DM, type 2 diabetes mellitus; PTB, pulmonary tuberculosis; HbA1c, glycosylated hemoglobin.

Comparison of imaging features in T2DM TB in patients with different HbA1c levels

Figure 1A shows that the upper lobe of the right lung has larger diameter of the exact shadow. In the three groups, the detection rate of large segmented leafy shadow (Figure 1B) was 50% (16/32), 56.2% (27/48), and 87% (87/100); the air bronchogram sign (Figure 1C) detection rate was 40.6% (13/32), 47.9% (23/48), and 77% (77/100); the discovery rate of mouth-eaten cavity (Figure 1D) was 31.2% (10/32), 45.8% (22/48), and 65% (65/100); thick wall cavity (Figure 1E) detection rate was 25% (8/32), 31.2% (15/48), and 52% (52/100); the rate of multiple cavities (Figure 1F) was 34.3% (11/32), 50% (24/48), and 73% (73/100); and bronchial TB (Figure 1G) was found in 33.3% (7/32), 21.8% (16/48), and 46% (46/100), respectively (Figure 2). The detection rates of lesions in Group III were significantly higher than in Group II and Group I ($p<0.05$), and the rate of discovery was significant ($p<0.05$) (Table 1). Meanwhile, the mean size of lesions in the three groups increased with the increasing of the HbA1c levels (Figure 3). After treatment, in the patients whose HbA1c level reached control target ($<7\%$) among the three groups, CT absorption improvement rates of 100% (32/32),

72.9% (35/48), 56% (56/100) were observed, respectively, (Figure 4). The therapeutic efficacy rate of group I was better than group II ($\chi^2=10.35$, $p<0.01$), and the treatment efficacy rate of group II was better than group III ($\chi^2=3.92$, $p<0.05$). The TB improvement rate of all groups increased progressively ($\chi^2=21.81$, $p<0.05$) (Figure 5, Table 2).

Discussion

In this single-center prospective cohort study, we compared the initial presentation and treatment response according to the diabetes control situation. In this study, we found that differences in imaging performance and response to treatment were associated with initial diabetic control status. Huang et al¹² evaluated the impact of glycemic status on CT findings of PTB in DM patients too. They suggested that glycemic status influenced radiological manifestations of PTB with DM and showed an increased risk of atypical radiological presentations of PTB in DM patients. Physicians should be alert enough to pay more attention to PTB patients with poor glycemic control. We found that the frequency of having cavities was positively associated with HbA1c levels. To the best of our knowledge, our study is the first prospective cohort study

designed to evaluate the correlation between CT features and HbA1c levels in patients with T2DM complicated with PTB. In our study, HbA1c $\geq 7\%$ is an independent risk factor for poor CT features in PTB patients. CT manifestations of

T2DM complicated with PTB were closely related to HbA1c level. The treatment effect is better when HbA1c level <7%. HbA1c level effectively reflects the severity and therapeutic effect to a certain extent. CT scan can provide some important information for clinical imaging.

Diabetes is considered to be associated with the late-onset cultural conversion and poor treatment outcomes in TB,^{3,9,14} although not all reports have shown a similar relationship.^{15,16} For anti-*Mycobacterium tuberculosis* antibiotics to effectively eliminate *M. tuberculosis*, a normal functioning immune system is required.¹⁷ One hypothesis is that chronic hyperglycemia can lead to immune dysfunction, thereby reducing the efficacy of anti-TB treatment; another possible reason is that diabetes can interact with anti-TB drugs.^{18–20} It is unclear whether glycemic control in the course of anti-TB treatment can affect the treatment of TB results. Several studies have suggested that more cavities are found in DM patients,^{21,22} especially in patients with poor blood glucose control (HbA1c $\geq 7.0\%$).²³ Another study showed that the degree of glycemic control in T2DM patients affected radiographic findings. In addition, cavities were associated with HbA1c levels.²⁴ The recent research found that poor glycemic control is associated with poor PTB treatment outcome.²⁵

This study also has some limitations. First, we did not obtain our target sample size, and so the relatively small number of cases may affect the results. Second, we did not compare T2DM PTB patients with just T2DM or PTB. Admittedly, a well-designed randomized controlled trial is needed

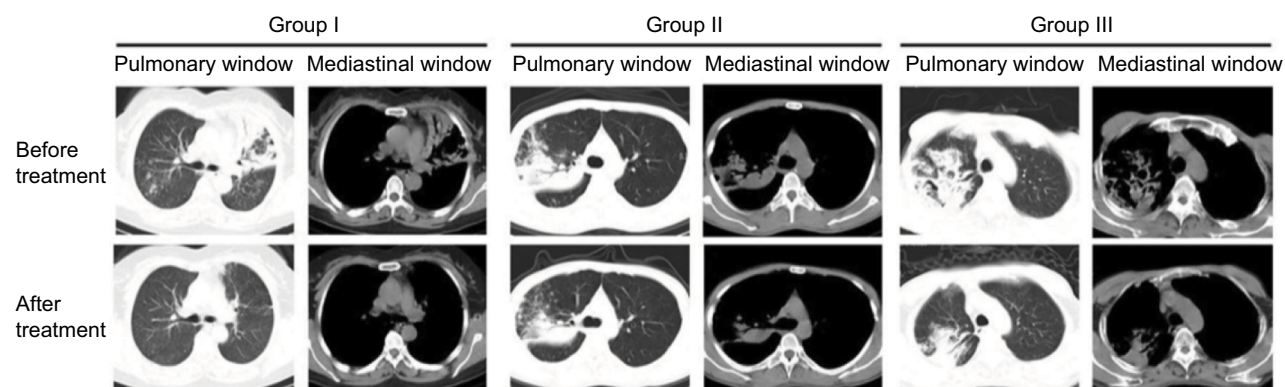

Figure 5 Chest radiograph signs in pulmonary window and mediastinal window before and after TB and T2DM treatment in three groups.

to show whether diabetic care intensification in the initiation of treatment of TB can improve the outcome of TB treatment.

Conclusion

CT manifestations of DM complicated with PTB were closely related to the level of HbA1c. If HbA1c standard <7%, the effect of TB treatment is better. HbA1c to a certain extent effectively reflects the severity and therapeutic effect of the disease; CT scan can provide some important information for clinical imaging. The above two examinations can guide clinicians to formulate the appropriate diagnosis and treatment in a timely manner.

Infection and Drug Resistance

Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of antibiotic

Submit your manuscript here: <https://www.dovepress.com/infection-and-drug-resistance-journal>

resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
