Background and aims: We aimed to evaluate the efficacy and tolerability of grazoprevir/elbasvir in patients with chronic genotype 1 hepatitis C virus (HCV) and HIV co-infection who experienced peginterferon alfa plus ribavirin (PegIFN/RBV) (clinicaltrials.gov NCT03098121).

Methods: This non-randomized, open-label trial study was conducted in Taoyuan General Hospital. HIV-infected patients were screened for HCV antibody since June 1, 2012, and HCV and HIV co-infected patients were tested for HCV RNA. The subjects who experienced PegIFN/RBV were enrolled in the study, and of whom with chronic genotype 1a or 1b received grazoprevir 100 mg and elbasvir 50 mg in a fixed-dose combination tablet once daily with or without ribavirin for 12 to 16 weeks.

Results: Of 2,419 HIV-infected patients, 40 patients with chronic genotype 1 HCV and HIV co-infection who failed PegIFN/RBV treatment were enrolled. Sixteen patients had genotype 1a and 24 patients had genotype 1b, with or without cirrhosis. The median age was 42 (41–47) years, and 5 patients (12.5%) were diagnosed with liver cirrhosis (child Pugh score A). The median CD4 count was 504 cells/ μ L (321–689). All patients (100%) had HIV viral load <200 copies/mL, and HCV viral load was 6.3 log₁₀ IU/mL (3.98–7.12). At the end of treatment, all patients (100%, 40/40) had undetectable HCV viral load, and 95.0% (38/40) of patients achieved sustained virologic response at 12 weeks.

Conclusion: Grazoprevir/elbasvir was effective in genotype 1 patients co-infected with HIV with or without cirrhosis. This finding is consistent with that of previous trials of this regimen in monoinfected population.

Introduction

Chronic hepatitis C is an important cause of liver-related morbidity and mortality worldwide,¹ and an estimated 2–3 million people are chronically infected with both hepatitis C virus (HCV) and human immunodeficiency virus (HIV).^{2–4} Patients who are coinfecting with HCV/HIV have higher baseline HCV viral loads, more rapid progression of liver disease,⁵ and higher rates of liver cirrhosis, hepatocellular carcinoma, and hepatic decompensation than patients monoinfected with HCV do.⁶ Although antiretroviral therapy (ART) significantly decreases HIV-associated morbidity, patients coinfecting

with HCV/HIV have higher rates of hepatic decompensation and liver failure than HCV-monoinfected patients.⁶

Hepatitis C genotype 1 is endemic in Asia (prevalence varies between 15% and 70% among all hepatitis C virus infections).⁷ Sustained virologic response (SVR) rate of peginterferon alfa plus ribavirin (PegIFN/RBV) was around 30–70% in patients with chronic genotype 1 HCV and HIV coinfection (HCV/HIV).^{7–10} In Taiwan, the prevalence rate of genotype 1 is around 45%,¹¹ and SVR rate of PegIFN/RBV for 48 weeks was 68%.¹² Direct-acting antivirals (DAAs) have revolutionized the treatment of HCV infection. High SVR rates (>90%) were reported with the combination of ombitasvir, dasabuvir, paritaprevir/ritonavir, and ribavirin (TURQUISE-1),¹³ daclatasvir plus sofosbuvir (ALLY-2),^{14,15} sofosbuvir/ledipasvir (ERADICATE, ION-4),^{16,17} grazoprevir/elbasvir (C-WORTHY, C-EDGE CO-INFECTION),^{18,19} and glecaprevir/pibrentasvir (EXPEDITION-2)²⁰ in patients coinfecting with HCV/HIV. These studies suggest that high rates of SVR are achievable in patients with HCV/HIV.

Grazoprevir/elbasvir was approved by the US Food and Drug Administration in 2016 for the treatment of HCV genotype 1 or 4 infection; however, HCV resistance testing of the NS5A region in genotype 1a-infected patients before grazoprevir/elbasvir therapy is essential. The guidelines recommend that HCV/HIV coinfecting patients must be treated and monitored primarily for drug–drug interactions (DDIs) with ART, and there are less DDIs between grazoprevir (NS3/4A protease inhibitor)/elbasvir (NS5A inhibitor) and ART.^{21,22} Hence, high rate of SVR was achieved and few adverse effects were documented in clinical trials, but reports on PegIFN/RBV-experienced and HCV/HIV co-infected cases in Asia are scarce. Therefore, in the present study, we aimed to evaluate the efficacy and tolerability of grazoprevir/elbasvir in patients with chronic genotype 1 HCV/HIV co-infection who experienced PegIFN/RBV.

Methods

This study is a prospective, single-center, and open-label clinical trial (NCT03098121). We performed a systemic screening of HCV antibody in all HIV-infected patients in Taoyuan General Hospital between June 1, 2012 and November 30, 2018 (Figure 1). HCV RNA testing was performed for patients with positive HCV antibody who received treatment with PegIFN/RBV.

Patients who failed PegIFN/RBV treatment were re-screened for HCV RNA and genotype, and patients with HCV RNA $\geq 10,000$ IU/mL and genotype 1a or 1b were enrolled to receive grazoprevir/elbasvir. Written informed

consent was obtained from all participants included in the study and the study protocol conforms to the ethical guidelines of the 1975 Declaration of Helsinki as reflected in a priori approval by the Research Ethics Committee or institutional review board of Taoyuan General Hospital.

Study population

HIV-infected men and non-pregnant women aged ≥ 18 years with HCV genotype 1 infection, who experienced PegIFN/RBV treatment, were eligible for grazoprevir/elbasvir treatment. Patients with HCV RNA $> 10,000$ IU/mL, stable ART with confirmed plasma HIV-1 RNA < 200 copies/mL, and CD4 T-cell count > 100 cells/ μ L were enrolled. Patients with compensated cirrhosis were also allowed to be enrolled. The exclusion criteria were as follows: patients with decompensated liver disease (presence or history of ascites, esophageal or gastric variceal bleeding, hepatic encephalopathy, or other signs of advanced liver diseases); liver cirrhosis with Child-Pugh class B or C, or with a Child-Turcotte-Pugh score of more than 6 points and albumin below 3 g/dL or platelet count below 75,000/ μ L; and hepatitis B virus coinfection.

Study procedures

This is a single arm and open-label clinical trial. All patients were prescribed grazoprevir/elbasvir with or without ribavirin, and the laboratory tests were performed at Taoyuan general hospital. Samples were assessed for HCV RNA at baseline, weeks 4, 12, and 16 (only for patients with genotype 1a) of treatment, and at follow-up week 12. Plasma HCV RNA viral loads were measured at Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan City, using Roche LightCycler RNA Master SYBR Green I/High Pure Viral Nucleic Acid Kit with a lower limit of quantitation of less than 10 IU/mL. HCV genotype was determined using Abbott HCV Real Time Genotype II assay (Abbott Diagnostics, Chicago, IL, USA). HIV RNA was measured with COBAS AmpliPrep/COBAS TaqMan HIV-1 test version 2.0 (Roche), with a lower limit of quantitation of less than 20 copies/mL. The method to detect RASs was Sanger sequencing, and emergent resistance variant testing was performed in patients with genotype 1a who experienced virologic failure. The written report only included the presence or absence of resistance-associated substitutions (RASs) in NS5A gene: M/L28T/A, Q/R30E/H/R/G/K/L/D, L31M/V/F, H58D, or Y93C/H/N.

The Fibrosis-4 (FIB-4) score is a non-invasive scoring system based on several laboratory tests that helps to estimate

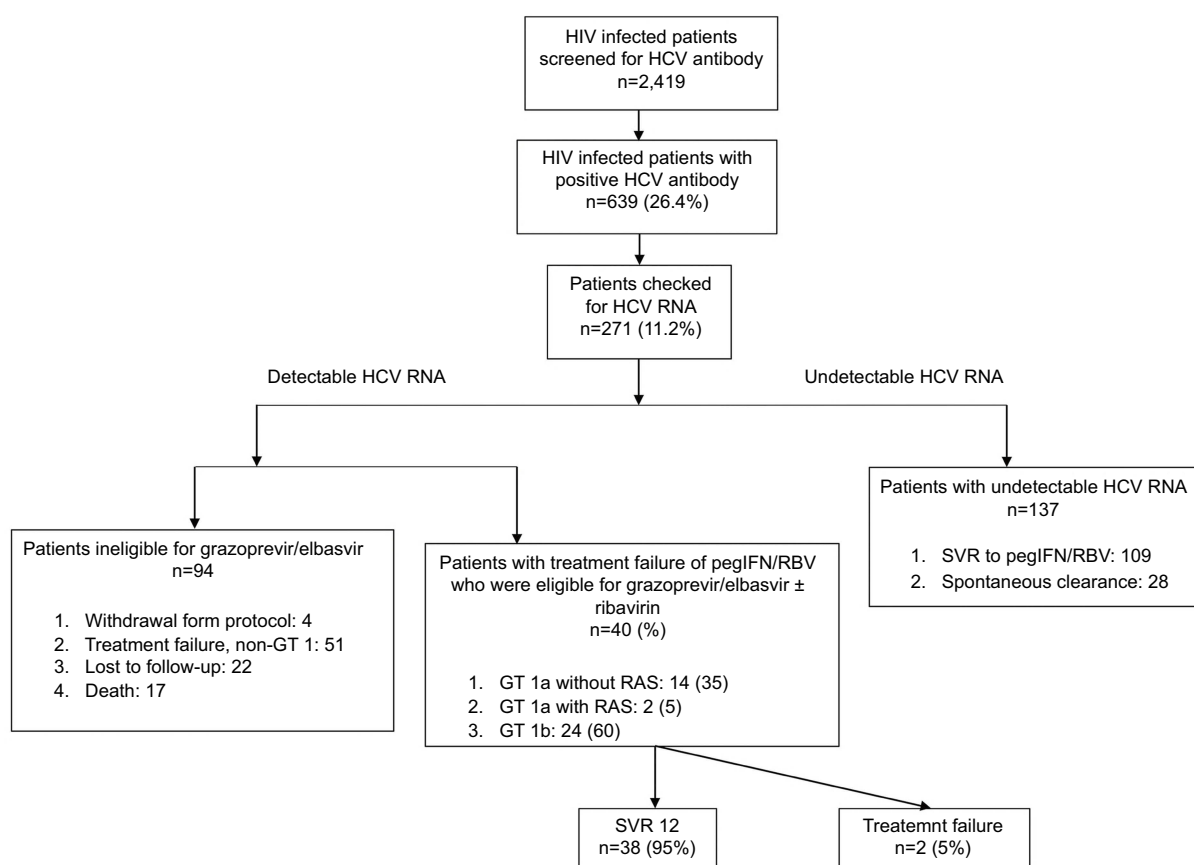

Figure 1 Flowchart of enrollment of patients with chronic genotype I HCV and HIV co-infection who failed peginterferon alpha plus ribavirin treatment.
Abbreviations: HCV, hepatitis C virus; GT, genotype; pegIFN/RBV, peginterferon alpha plus ribavirin; SVR, sustained virologic response.

the amount of scarring in the liver.^{23,24} This score was assessed in liver disease due to hepatitis C and nonalcoholic steatohepatitis, and the fibrosis status of patients was presented with FIB-4 score in our study. Tolerability was assessed through monitoring of adverse events, vital signs, and laboratory parameters. The events of clinical interest were first instance of alanine aminotransferase (ALT) or aspartate aminotransferase (AST) more than three times the upper limit of normal values and more than 100 U/L. Samples were taken from all patients at baseline and at the time of failure in patients who met the virologic failure criteria (HCV RNA concentration more than the lower limit of quantitation measured from two separate blood draws within 2 weeks).

Study treatment

Patients with chronic genotype 1a, with or without RASs in NS5A gene, received grazoprevir 100 mg and elbasvir 50 mg in a fixed-dose combination tablet once daily with ribavirin for 16 weeks. Patients with chronic genotype 1b

received grazoprevir 100 mg and elbasvir 50 mg in a fixed-dose combination tablet once daily for 12 weeks.

Statistical analysis

Efficacy and safety analyses were performed using data from the per-protocol population, which was defined as all patients who completed the study drug treatment. The number and percentage of patients achieving efficacy endpoints of sustained virologic response at 12 weeks (SVR 12) were summarized, and the corresponding 95% confidence intervals (CIs) were calculated. Adverse events and laboratory values were summarized for each treatment group (Table 3). The statistical significance of the difference between groups was determined using χ^2 tests for categorical variables and using Student's *t*-tests for two independent means for quantitative variables. The cutoff for statistical significance was set at $p \leq 0.05$. The statistical analyses were performed with SPSS 19.0 software (SPSS Inc., Chicago, IL, USA).

Results

Grazoprevir/elbasvir treatment

Overall, 2,419 HIV-infected patients were screened for HCV antibody during a clinical visit from June 1, 2012. Among them, 639 patients (26.4%) were found to have positive HCV antibody. Of these 639 patients, 271 patients (11.2%) were tested for HCV RNA (Figure 1). One hundred and thirty-seven patients had undetectable HCV RNA, of whom, 109 patients had SVR due to PegIFN/RBV treatment and 28 patients had spontaneous clearance. Among 134 patients with detectable HCV RNA, 94 patients were ineligible for grazoprevir/elbasvir treatment. Among these 94 patients, 51 patients who experienced treatment failure with PegIFN/RBV were non-genotype 1, 22 patients lost to follow-up, and 17 patients died. Forty patients were eligible for grazoprevir/elbasvir treatment, of whom, 14 patients (35%) had genotype 1a without RAS, 2 patients (5%) had genotype 1a with RASs, and 24 patients (60%) had genotype 1b (Figure 1).

Patient characteristics

The first patient started treatment on July 24, 2017, and the last patient completed 12 weeks of follow-up on November 8, 2018. The baseline characteristics are presented in Table 1. Most of the patients were men (92.5%) and intravenous drug users (92.5%). The median patient age was 42 years, and the median CD4 cell count was 504 cells/ μ L. Thirty-six patients (90%) had HIV RNA <50 copies/mL. Twenty-two patients (55%) received emtricitabine and tenofovir disoproxil fumarate, and 17 patients (42.5%) received lamivudine and abacavir as ART, along with rilpivirine (n=20, 50%), dolutegravir (n=17, 42.5%), or raltegravir (n=2, 5%). Twenty-eight patients (70%) experienced relapse or re-infection from previous PegIFN/RBV, and 12 patients (30%) withheld treatment due to toxicity of PegIFN/RBV. Overall, 31 patients (77.5%) had HCV RNA levels >800 000 IU/mL and 5 patients (12.5%) had FIB-4 score >3.25.

Treatment outcome

Overall, SVR12 was achieved in 38 of 40 patients (95%) (Figure 1). Two patients relapsed after having undetectable HCV RNA concentrations at the end of treatment. The relapsed patients were non-cirrhotic and included one patient with HCV genotype 1a infection and one patient with HCV genotype 1b infection at enrollment.

Table 1 Baseline characteristics of patients with chronic genotype 1 HCV and HIV co-infection who failed peginterferon alfa plus ribavirin treatment

Abbreviations: ULN, upper limit of normal; RBV, ribavirin.

week 12). In the analysis, first patient was classified as relapsed, but sequencing data were consistent with reinfection after treatment.

Two of 16 genotype 1a-infected patients (12.5%) harbored baseline RASs in NS5A gene, and the specific RASs detected in these two patients were Met28Val (M28V; two patients) and Leu31Met (L31M; one patient) (Table 2). In these patients, the presence of NS5A RASs at baseline did not reduce SVR12 rates. The SVR12 rates were 100% in patients with baseline NS5A RASs (Table 2).

Safety and tolerability

Of 20 patients with FIB-4>1.45 at baseline, the median FIB-4 was 2.9. The FIB-4 score was 1.6 at week 4 ($p=0.025$), 0.8 at end of treatment (EOT), and 0.71 at SVR12 (Figure 2). Overall, two serious adverse events and 57 adverse events occurred. These two serious adverse events were classified as ribavirin-related anemia (Grade 3). Among possible drug-related clinical adverse events, the most common events were fatigue (n=11; 27.5%), depression (n=6; 15%), and nausea or vomiting (n=6; 15%) (Table 3). Among laboratory adverse events, there were two (5%) Grade 3 adverse events.

Figure 2 Improvement of fibrosis-4 score after treatment of grazoprevir and elbasvir with or without ribavirin.

Abbreviations: EOT, end of treatment; SVR 12, sustained virologic response at 12 week.

We noted no late elevations in ALT or AST levels. There was no discontinuation of the study drug in the whole study population. Among the 16 patients who received ribavirin, two cases of drug-related anemia occurred, following which ribavirin dose was reduced to 50%.

Discussion

In this non-randomized, open-label clinical trial, we aimed to evaluate the efficacy and tolerability of grazoprevir/elbasvir in patients with chronic genotype 1 HCV and HIV co-infection who experienced PegIFN/RBV. We found that once-daily administration of grazoprevir/elbasvir for 12–16 weeks, with or without ribavirin, had a very high SVR12 rate of 95% and showed an excellent safety profile in patients with chronic genotype 1 HCV and HIV co-infection who failed PegIFN/RBV.

HCV treatment should be a priority for patients with HCV/HIV co-infection.²¹ Efficacy and adverse event rates of HCV DAAs in patients with HCV/HIV co-infection were similar to those observed in patients with HCV alone.^{14,16,19,20}

HIV/HCV co-infected patients are not considered a special population anymore, although there are certain barriers to DAA therapy in these patients. High rates of HCV relapse or re-infection are observed, and dedicated care is required in the management of HIV/HCV co-infected patients with special social and behavioral issues or drug–drug interactions, especially people who inject drugs (PWID).²⁵ In our study, majority of the patients belonged to PWID category ($n=37$, 92.5%), and SVR12 rate of 94.6% ($n=35$) was achieved. Grazoprevir/elbasvir plus ribavirin was administered for 16 weeks in all PegIFN/RBV failure patients with chronic genotype 1a with or without RASs in our study, and no relapse was identified. Only two patients failed to achieve SVR12, but they showed good adherence to grazoprevir/elbasvir throughout the study. One patient had an HCV viral load of 5.5 log RNA (292,288 IU/mL and genotype 1a at enrollment), and he achieved undetectable viral loads (<10 IU/mL) at week 4 and week 16 (end of treatment); however, genotype 6 with an HCV viral load of 2.6 log RNA (377 IU/mL) was detected at week 28 (at follow-up week 12). It was hard to distinguish between re-infection and mixed infection at enrollment for this patient, because HCV RNA was only 377 IU/mL. Although our method (Roche LightCycler RNA Master SYBR Green I/High Pure Viral Nucleic Acid Kit) could detect HCV RNA with a lower limit of quantitation of less than 10 IU/mL, only one dominant strain can be identified; however, the prevalence of mixed infection among PWID ranges from 14% to 39%.²⁶ In Taiwan, the prevalence rate of genotype 6 was around 28.0% among PWID with chronic HCV/HIV infection.¹¹ Hence, next-generation sequencing may be more suitable to identify mixed infection of HCV before treatment in this population.²⁷ The other patient had an HCV viral load of 4.8 log RNA (68,966 IU/mL and genotype 1b at enrollment), and he achieved undetectable viral loads (<10 IU/mL) at week 4 and week 12 (end of treatment); however, genotype 1b with 3.9 log RNA (2,202 IU/mL) was detectable at week 24 (at follow-up week 12). In most clinical trials and real-world data demonstrating high SVR12 in genotype 1b infection,^{16–20,28} most of the treatment failures were identified as re-infection or lost to follow-up. Therefore, we could not exclude the possibility of re-infection in the second patient with genotype 1b at follow-up week 12. In our study, dolutegravir, rilpivirine, or raltegravir in combination with a nucleoside or nucleotide reverse transcriptase inhibitor was prescribed as concurrent ART. No association was observed between relapse and ART regimen, suggesting that plasma concentrations of grazoprevir/elbasvir were not affected by ART.

Overall, grazoprevir/elbasvir-based treatment was safe. More adverse events were observed in patients treated with ribavirin than that in patients treated without ribavirin. Serious adverse events (anemia caused by ribavirin) occurred in only two patients (5%), but treatment discontinuation was not reported. These data are similar to those reported in other studies.^{16–20,29}

Most of the patients were PWID in our study (92.5%), and 87.5% of them revealed a FIB-4 score of <3.25. In Taiwan, until December 2018, treatment with the newest HCV DAAs was restricted to patients with a FIB-4 score of >3.25, owing to the high cost of these drugs. Hence, for majority of coinfecting patients in Taiwan, DAA treatment was not covered by national health insurance by December 2018. This study offered HCV treatment with grazoprevir-elbasvir to patients with chronic genotype 1 HCV/HIV co-infection who experienced PegIFN/RBV, regardless of their fibrosis stage. By providing HCV treatment access to high-risk population or all HCV-infected patients, we were able to reduce transmission of HCV to other PWID or their sexual partners, as well as the deterioration of liver-associated morbidities or mortalities.³⁰ Fortunately, the Bureau of National Health Insurance launched DAA therapy for all HCV-infected patients in Taiwan since January 2019.

There are several limitations to our study. First, it was designed in an era when open-label single-arm studies with a historical control were acceptable for the assessment of DAA agents. This study design is consistent with other recent non-randomized phase 3 studies.^{7,10} Second, although there is no comparator, it is important to note the difference from the C-EDGE CO-INFECTION study,¹⁹ because patients with chronic genotype 1 HCV/HIV co-infection who experienced PegIFN/RBV were enrolled in our study, and efficacy was similar. Third, the sample size might be too small to support primary efficacy analysis, and all patients were enrolled in one study site; hence, the outcome cannot be extrapolated to patients from other clinical settings, such as China. Fourth, the population sequencing method also has one limitation. Although it can be used in samples from patients with a viral load of more than 20 IU/mL, it is not capable of detecting variants that represent less than 25% of the total viral population.

In conclusion, our study showed that once-daily grazoprevir/elbasvir with or without ribavirin for 12 or 16 weeks is effective for genotype 1 patients co-infected with HIV with or without cirrhosis who experienced PegIFN/RBV, including the important subpopulation of people

who inject drugs (PWID). These data are consistent with those of previous trials using this regimen in the mono-infected population.

Data sharing statement on clinical trial data

Our authors will share individual participant data collected during the trial after de-identification, including study protocol and analysis plan. Data should be directed to s841060@gm.ym.edu.tw. To gain access, data requestors will need to sign a data access agreement, and data will be made available immediately after publication. No end date.

Abbreviations list

Infection and Drug Resistance

Dovepress

Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of

antibiotic resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
