Background: Dynein axonemal assembly factor 2 (*DNAAF2*) is involved in the early preassembly of dynein in the cytoplasm, which is essential for motile cilia function. Primary ciliary dyskinesia (PCD) associated with *DNAAF2* variants has rarely been reported in females with infertility. Moreover, there is no report linking *DNAAF2* to scoliosis in human.

Materials and Methods: We recruited patients from two consanguineous families with a clinical diagnosis of PCD and collected their clinical history, laboratory tests, and radiographic data. Sequencing and bioinformatics analysis were then performed. Immunofluorescence and high-speed microscope analysis were used to support the pathogenicity of the variant.

Results: Proband 1, a 26-year-old female from family I, exhibited scoliosis, bronchiectasis, sinusitis, situs inversus, and infertility. We found a novel homozygous missense variant in *DNAAF2*, c.491T>C, p.(Leu164Pro) in this patient. Subsequent immunofluorescence indicated the absence of outer dynein arm and inner dynein arm of cilia, and high-speed microscopy analysis showed that the most of the cilia are static, which support the pathogenicity of this variant. Proband 2, a 53-year-old female, presented with bronchiectasis, sinusitis, and infertility. In this patient, a new homozygous frameshift variant *DNAAF2*, c.822del, p.(Ala275Profs*10) was identified. The disease-causing variants mentioned above are not included in the current authorized genetic databases.

Conclusion: Our findings expand the spectrum of *DNAAF2* variants and link *DNAAF2* to female infertility and likely scoliosis in patients with PCD.

Keywords: primary ciliary dyskinesia, scoliosis, *DNAAF2*, bronchiectasis, situs inversus, female infertility

Introduction

Primary ciliary dyskinesia (PCD, MIM:244400) is a rare genetically heterogeneous disorder.¹ It has a variety of clinical manifestations, such as chronic otorhinolaryngological diseases, male and/or female infertility and laterality defects, etc.^{2,3} More than 50 genes have reported to cause PCD,⁴ but detailed clinical evaluation has rarely conducted in adult patients with PCD, especially the phenotype associated with infertility.⁵

Changes in motile cilia are closely associated with PCD, and recent studies have shown that dysfunction of ependymal motile cilia can influence the flow of cerebrospinal fluid and possibly result in spinal dysplasia, eventually leading to

scoliosis in zebrafish.⁶ Scoliosis is defined as a spinal deformity in a skeletally mature patient with a Cobb angle of more than 10 degrees in the coronal plane.⁷ Dynein axonemal assembly factor 2 (*DNAAF2*), involved in the early preassembly of dynein in the cytoplasm, is essential for motile cilia function^{8,9} and may be related to adult scoliosis.

Here, we analyzed the exome and clinical data of two individuals who were diagnosed with PCD. In our study, we validate the pathogenicity of a missense variant through immunofluorescence and high-speed microscope analysis, and link *DNAAF2* variants to female infertility and likely scoliosis.

Materials and Methods

Ethical Compliance

The Review Board of the Second Xiangya Hospital of Central South University in China approved the study protocol. This study was conducted in accordance with

the Declaration of Helsinki. The patients and their parents were given informed consent. All experiments were strictly following the relevant guidelines and provisions. We recruited patients coming from two consanguineous families. The clinical data of the subjects, including nasal nitric oxide (nNO) level, computed tomography (CT) and chest radiographs were collected for reviewing.

Measurement of nNO

Nasal NO was measured using an electrochemical NO analyzer, Sunvou-CA2122 nitric oxide analyzer (Sunvou, China). Patients maintain positive oral pressure by blowing into a mouth resistor as described.¹⁰ The sensor converted the NO content of the nasal sampling into current and then the concentration of NO was calculated. We converted NO concentration into NO production rate by following equation: $nNO(nL/min) = NO(ppb) \times \text{samplingrate}(mL/min)$.

Figure 1 (A) Pedigree of the family 1 and Sanger sequencing chromatogram of proband 1 and her parents. A novel variant *DNAAF2* c.419T>C, p.(Leu164Pro) was identified in the proband. Her parents were heterozygous at the same position. **(B)** Pedigree of the family 2 and Sanger DNA sequencing chromatogram of proband 2. A novel variant *DNAAF2* c.822delA, p.(Ala275Profs*10) was identified in the proband. Circles indicate to females. Squares indicate males. Solid symbols indicate patients. Crossed-out symbols mean that subjects had passed away. The arrows indicate the probands. The vertical line with 2 hash marks at the end indicates infertility.

Variant Analysis

Blood samples (3–5mL) were collected from the probands and their relatives. We used the DNeasy Blood & Tissue Kit (Qiagen, Valencia, CA) to extract genomic DNA. The Novogene Bioinformatics Institute (Beijing, China) carried out the Whole-exome capture and high-throughput sequencing. The Agilent SureSelect Human All Exon V6 kit (Agilent, California, USA) was used to set up the library and capture the whole exomes. High-throughput and high-depth sequencing was performed on Illumina platform. Sequencing reads were mapped to the human reference genome (GRCh37/hg19). ANNOVAR software¹¹ was used to annotate the data. Then, we classified the variants referring to the standards and guidelines for the interpretation of sequence variations from The American College of Medical Genetics (ACMG).¹² Pathogenicity screening was performed on the single-nucleotide variants (SNVs)/insertion and deletions (InDels) information detected by basic analysis: 1) High-frequency variants (minor allele frequency > 0.01) in 1000 genome data (1000G_ALL), ESP6500 database (ESP6500si_all), gnomAD data (gnomAD_ALL and gnomAD_EAS) were removed to obtain rare variants. 2) Preserve variants in coding regions (exonic) or splicing site regions (splicing, up and down 10bp). 3) SIFT, Polyphen-2, MutationTaster and CADD were used to screen non-synonymous SNVs. Sanger sequencing was used to validate the candidate variants. The primer sequences for Sanger sequencing were as follows: proband 1,

forward 5'-GTGGAAGTGCGGTTCTGT-3' revers 5'-TATACTTGGCCTTCAGGGTCT-3'; proband 2, forward 5'-GCCGTCGAGAAGCAGTT-3' reverse 5'-GTAGTCAGGTTTCCTCGAGTC-3'.

Immunofluorescence and High-Speed Microscopy Analysis

Nasal brushing sample was suspended in Gibco Medium 199 (12350039 Gibco). We used anti-acetylated tubulin monoclonal antibody (T7451, 1:500, Sigma-Aldrich, Missouri, USA) to mark the ciliary axoneme, DNAH5 (HPA037470, 1:100, Sigma-Aldrich, Missouri, USA) to label the outer dynein arm (ODA), DNALI1 (HPA028305, 1:10, Sigma-Aldrich, Missouri, USA) to label the inner dynein arm (IDA) and DAPI to label the nuclei. Immunofluorescence was used to profile the ciliary structure of patients with *DNAAF2* variants. Cilia beating video was recorded at 500 frames/second at room temperature by scientific complementary metal oxide semiconductor (sCMOS) camera (Prime BSI, Teledyne Photometrics Inc, USA) attached to an upright Olympus BX53 microscope (Olympus, Tokyo, Japan) with a 40× objective.

Homozygosity Mapping

We use a high-performance homozygosity mapping tool¹³ and next-generation sequencing data of proband 1 and proband 2 to map the homozygous gene distribution.

Figure 2 Clinical features of two patients in two consanguineous families. **(A)** Radiographic image of proband 1 with bronchiectasis showed right left-sided lumbar scoliosis with a Cobb's angle of 13.5°. **(B and C)** The chest high-resolution computed tomography (HRCT) scan of proband 1 showed bronchiectasis and the situs inversus. **(D and E)** The chest HRCT scan of proband 2 showed bronchiectasis.

Table 1 Summary of the Clinical Features of Two Patients with PCD

Characteristics	Proband 1	Proband 2
Sex	Female	Female
Age (years)	26	53
Onset	Childhood	Unknown

Results
Clinical Summary

Proband 1, a 26-year-old female from consanguineous family-I ([Figure 1A](#), [Supplementary Figure 1](#)), had scoliosis, bronchiectasis, sinusitis, situs inversus and infertility. She denied any history of asthma, immunodeficiency, measles, tuberculosis, etc. Her family members had no similar symptoms or history of respiratory disease. High-resolution CT (HRCT) revealed diffuse bronchiectasis and situs inversus and upright radiograph indicated a Cobb's angle of 13.5° ([Figure 2A–C](#)). Her nasal NO output level

was 25.2 nL/min ([Table 1](#)). Proband 2, a 53-year-old female from consanguineous family-II ([Figure 1B](#)), had bronchiectasis ([Figure 2D and E](#)), sinusitis and infertility. HRCT revealed diffuse bronchiectasis. The nasal NO output level was 2.4 nL/min ([Table 1](#)).

Whole-Exome Sequencing and Functional Study for the *DNAAF2* Variants

More than 10Gb data were generated for each sample after whole-exome sequencing (WES). Appropriately 99% of the gene with a depth of more than 10× were mapped to the reference genes. Through alignment and frequency filtering, we further analyzed the non-synonymous variants (SNVs and InDels) and variants in exons or in canonical splice sites (splicing junction 10 bp). Then, we filtered the homozygous SNVs and InDels. Ultimately, we screened two different homozygous *DNAAF2* variants, NC_000014.8:g.50101377A>G, NM_018139.3:c.491T>C, NP_001077377.1:p.(Leu164Pro) and NC_000014.8:g.50101046del, NM_018139.3:c.822del, NP_001077377.1: p.(Ala275Profs*10) from two consanguineous families. The missense variant was predicted to be disease-causing by SIFT, Polyphen-2, MutationTaster and CADD. The two variants were classified as likely pathogenic according to ACMG guideline ([Table 2](#)). Both variants were consistent with the family inheritance pattern, and verified by Sanger sequencing ([Figure 1](#)). Segregation of the variant *DNAAF2*, c.491T>C, p.(Leu164Pro) in two healthy sisters of proband 1 was also validated by Sanger sequencing ([Supplementary Figure 1](#)). Homozygosity mapping confirmed the homozygous region in chromosome 14 contains the variants of *DNAAF2* in proband 1 and proband 2 ([Figure 3](#)). Immunofluorescence of nasal ciliated cells of proband 1 revealed the absence of ODA ([Figure 4](#)). High-speed microscopy showed that the most of the nasal cilia are static in Proband1 compared with the normal control ([Supplementary Video 1](#) and [Supplementary Video 2](#)).

Abbreviation: NA, not available.

Discussion

In this study, whole-exome sequencing combined with homozygosity mapping was used to identify homozygous variants in *DNAAF* in two consanguineous families. The two novel variants were validated to be disease causing by using immunofluorescence and high-speed microscope analysis. These two female patients presented with infertility; moreover, upright radiograph in one patient revealed scoliosis.

PCD is a genetic ciliopathy caused by dysfunction of respiratory motile cilia and failure of mucociliary clearance.¹⁴ The respiratory manifestations include neonatal respiratory distress, chronic rhinosinusitis, otitis media, and bronchiectasis. Cilia in other organs can be involved, such as embryonic node, female fallopian tubes, sperm, and ependymal cells.

DNAAF2 is involved in the early preassembly of dynein in the cytoplasm, which is essential for motile cilia function.^{2,8,9,15} Deficiency of the protein can lead to loss of inner and outer dynein in cilia axoneme, and cilia beating defect. Multiple *DNAAF2* variants: c.23C>A,

c.26C>A, c.31delG, c.472G>T, c.564dupG, c.998C>T, c.1160A>G, c.1199_1214dup16, c.1555delG, c.1891G>A, c.1901T>C and c.2027_2028delCT have been reported to be associated with PCD^{9,16–24} (Figure 5). Two novel *DNAAF2* variants were identified and confirmed to caused PCD in our patients through exome sequencing, immunofluorescence, and high-speed microscopy analysis. Situs inversus and male infertility have been previously reported due to *DNAAF2* variants. No immunoreactivity for the ODA marker DNAI1 and DNAI2 in sperm flagella was observed for *DNAAF2*-mutant individuals. Sperm flagellar length is significantly reduced in *DNAAF2*-mutant males.²⁵ However, female infertility and scoliosis has not been investigated in patients with *DNAAF2* variant due to fallopian tubes and ependymal cells involved. Both Our patients both exhibited chronic sinusitis, bronchiectasis, reduced nNO production rate and female infertility, and one patient also presented with situs inversus and scoliosis.

Female infertility is reported less common than male infertility for PCD patients, which may relate to the

Figure 3 Homozygosity mapping using AutoMap software to detect regions of homozygosity (ROHs) larger than 2 Mb. ROHs are shown in blue for proband 1 and proband 2. The homozygous regions were shown in blue for proband 1 and proband 2 and the regions containing the *DNAAF2* gene were marked with arrows.

Figure 4 Immunofluorescence of nasal ciliated cells revealed the absence of DNAH5 and DNALI1 of proband 1. Anti-acetylated tubulin monoclonal antibody was used to mark the ciliary axoneme. DNAH5 was used to label the outer dynein arm (ODA), DNALI1 was used to label the inner dynein arm (IDA) and DAPI was used to label the nuclei.

difficult in functional assessment of the cilia in fallopian tubes. In one study,²⁶ 22 of 36 adult female patients with PCD presented with infertile. However, as the genetic

heterogeneous in PCD, only a subset of PCD associated genes have been evaluated in the study. The phenotype of fertility in patient with *DNAAF2* variant was not

Figure 5 DNAAF2 protein structure and the reported disease-causing variants of DNAAF2. The novel variants reported in this study are highlighted in red.

established. The effect of cilia-related genes on female fertility may relate to the selective expression of genes in fallopian tubes. Cilia are located at the top of fallopian tube mucosa and is one of the main components of the mucosa. Coordinated ciliary movements in conjunction with muscle contractions transport egg cells through the fallopian tubes to the uterus, which is important to natural pregnancy.^{4,27} Human nasal cilia and fallopian tube cilia have similar structures.²⁸ As female patients with other dynein assembly factor variants such as *DNAAF1* and *LRRC6* were 100% infertile in the cohort,²⁶ we can infer that female infertility observed in proband 1 and proband 2 was due to *DNAAF2* deficiency and dysmotility of fallopian tube cilia. Further research was warrant to recapture and investigate the underlying mechanism of the phenotype in animal and human genetic studies.

Scoliosis was observed in several animal models with PCD-related gene mutations, such as *DNAAF4*, *ODAD3*, *CCDC40*, and *ZMYND10*.^{6,29} However, scoliosis has rarely reported in patients with PCD. In 198 PCD patients collected by Schlösser et al, it was found that patients with Cobb angle greater than 10° accounted for 8%, but they only evaluated the chest radiographs and the genetic diagnosis was not analyzed.³⁰ The etiology of idiopathic scoliosis remains unknown and the curvature of the spine is highly variable.^{7,31,32} The effect of abnormal cilia function is one of the possible reasons. Bearce et al believe that motile cilia, cerebrospinal fluid contacting neuron, the Reissner fiber and Urotensin neuropeptide signals constitute a “sensory organ” to sense the growth and development of the body axis.³³ There is another hypothesis that the spine will follow its pre-existent rotational pattern if it decompensates into an idiopathic scoliosis. It means that scoliosis in adult PCD patients with situs inversus may also result from decompensation of the spine that due to situs inversus rather than as a single result of early ciliary movement.³⁰ Although there are no reports mentioned scoliosis and cilia abnormality at the same time, the same gene is reported to be related to scoliosis or cilia abnormality in some articles.^{34–40} In our patient, *DNAAF2* variant impaired cilia motility, leading to situs versus, and may be related to her scoliosis phenotype. In future, to explore the causes of scoliosis in patients with PCD will help to raise the public’s attention to the spinal health, and carry out early intervention on spinal abnormality.

It should be noted that our study has examined only two patients with female infertility and one patient with scoliosis, and no intervention has been conducted. In vitro

fertilization may be effective to treat infertility in female patients with PCD as previously reported. Although the phenotype of scoliosis has been observed in several PCD animal models, scoliosis has rarely been evaluated in human genetic studies. Whether *DNAAF2* variant leads to scoliosis needs further validation.

In summary, we identified and validated the pathogenicity of two novel homozygous variants of *DNAAF2*, p.(Leu164Pro) and p.(Ala275Profs*10). Our findings expand the spectrum of *DNAAF2* variants. Furthermore, we propose a link between female infertility, likely scoliosis, and *DNAAF2* deficiency.

Data Sharing Statement

The data that support the findings of this study are available from the corresponding authors, Hong Luo and Ting Guo, upon reasonable request.

Ethics Statement

The studies involving human participants were reviewed and approved by the Review Board of the Second Xiangya Hospital of Central South University in China. Written informed consent to participate in this study was provided by the participants’ legal guardian/next of kin. Written informed consent was obtained from the individual(s), and minor(s)’ legal guardian/next of kin, for the publication of any potentially identifiable images or data included in this article.

Acknowledgments

We thank the patients and their families who participated in this study.

Pharmacogenomics and Personalized Medicine

Dovepress

Publish your work in this journal

Pharmacogenomics and Personalized Medicine is an international, peer-reviewed, open access journal characterizing the influence of genotype on pharmacology leading to the development of personalized treatment programs and individualized drug selection for improved safety, efficacy and sustainability. This journal is indexed

on the American Chemical Society's Chemical Abstracts Service (CAS). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
