Purpose: Accumulating research suggests that psychotherapy helps improve abstinence but the difference in the efficacy of multiple psychotherapies in alcohol use disorder (AUD) remains to be explored.

Patients and Methods: A systematic search of databases (Pubmed, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and EBSCO) for studies (published from inception to April 10th.) of adults diagnosed with AUD accepting psychotherapies was conducted. Studies covering 9 countries and regions. The qualitative analysis pooled 2646 individuals from 34 randomized controlled trials (RCTs) and the networks included 1928 participants (23 RCTs). The outcomes included percentage of days abstinent (PDA), change in drinks per drinking day (change in DDD), and change in craving compared among individuals accepting various psychotherapies. The protocol followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), and was registered on the International Prospective Register of Systematic Reviews (PROSPERO).

Results: For the network of PDA, motivational enhancement treatment (MET) (35.44, 11.78 to 59.09, high-certainty) and couple therapy (CT) (28.89, 13.42 to 44.36, moderate-certainty) were significantly different from treatment as usual (TAU) with the surface under the cumulative ranking curve (SUCRA) mean rank 1.9 and 1.9 respectively. TAU+supportive psychotherapy (SP) was better than TAU for the change in DDD in the high-quality direct comparison.

Conclusion: The motivational enhancement and the couple therapy show potential amelioration for alcohol abstinence. Additionally, the preferred interventions are different for improving PDA and change in DDD. The evidence network remains to be strengthened.

Keywords: alcohol use disorder, psychotherapy, randomized controlled trial, systematic review, network meta-analysis

Introduction

Alcohol use disorder (AUD) is one of the most common and far-reaching diseases in the current world, increasingly becoming an important public health and social problem. According to the latest global report, alcohol exposure showed an increasing trend in the world. AUD is not only the main cause of the morbidity and mortality burden of various diseases but also the source of intricate effects on mental health.^{1,2} However, former studies showed that the AUD population has not received sufficient and effective treatment yet,^{3,4} and it is expected that by 2030, drinking in many

regions will continue to increase. Therefore, it is emphasized that cost-effective policies and interventions should be formulated to increase awareness of alcohol risks and reduce consumption.²

AUD usually requires comprehensive intervention to improve both adherence and effectiveness. Control impairment of alcohol use is regarded as an important criterion grouping of pathological models for the diagnosis of substance use disorders: consumption out of control, failed abstinence attempts, craving, and burden derived from seeking.⁵ When exposed to alcohol-related stimuli, the behavioral effects of brain changes may manifest as repeated relapses and compulsion. Experts^{6,7} believe that abstinence management involves not only pharmacotherapy but psychotherapy because it is beneficial to help internalize changes in attitudes and behaviors that favor preventing relapse⁸ with fewer adverse effects and ethical objections but better compliance and affordability than medication treatment.⁹

Although many clinical studies were on psychotherapy alone or in combination for AUD, most systematic reviews and meta-analyses have only used internal comparisons of cognitive behavioral therapy (CBT),^{10–12} motivational enhancement treatment (MET),¹³ couple therapy (CT),¹⁴ and mindfulness-oriented therapy (MOT),¹⁵ and some conducted a large-scale meta-comparison referred to addiction diseases in general or included mixed study types.¹⁶ However, there is no network comparison of randomized controlled trials (RCTs) of multiple types of psychological intervention for AUD and it is unclear which type results in better outcomes. This study conducted a systematic review and network meta-analysis (NMA) of psychotherapies for AUD, which will provide a reference for clinical application and evidence-based research directions of psychotherapy for AUD.

Methods

The meta-analysis was conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and we used the PRISMA checklist when reporting ([Table S1](#)).¹⁷ This protocol has been registered at PROSPERO under registration number CRD42021259428.

Study Inclusion Criteria

All relevant studies were considered eligible if they included the following: randomization; an appropriate comparison group (ie, treatment as usual, usual care, or another active treatment); adult patients (aged 18+) diagnosed with AUD, AD, or alcohol abuse^{5,18–23} (details found in [Table S2](#)); participants receiving a form of psychotherapy ([S3](#)), defined by the American Psychiatric Association (APA),²⁴ and classified using the Nottingham Classification of Psychotherapies ([Figure S3](#)), as a single or major intervention or as an auxiliary means of integration; assessment of the percentage of days abstinent (PDA), the change in drinks per drinking day (change in DDD) and the change in craving using a validated measure.

PDA was used to measure the self-control and was assessed by Timeline Followback Interviews (TLFBs) or Form-90.²⁵ To some extent, the higher the PDA is, the better the patient's ability to control drinking is. Change in DDD was assessed by TLFBs or Form-90 to evaluate the change in average drinking on a drinking day, using a “standard drink” as a measure. Change in craving was assessed from the Desire for Alcohol Questionnaire (DAQ), Obsessive-Compulsive Drinking Scale (OCDS), three Likert-type scale items, the Alcohol Craving Questionnaire (ACQ), and the Penn Alcohol Craving Scale (PACS).²⁶ Craving is defined by The Diagnostic and Statistical Manual of Mental Disorders, the 5th version (DSM-V) as an intense desire or urge for the drug, which may occur at any moment, especially when one is exposed to an environment where the alcohol previously was obtained or used;²¹ higher scores on all scales above indicate a higher level of craving.

Database and Search Strategy

We systematically searched MEDLINE, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and APA PsycArticles & PsycInfo via EBSCO Databases (published from inception to Apr. 2022). Searches terms about disorders and interventions included alcoholism, alcohol dependence, alcohol addiction, alcohol use disorder, psychotherapy, sensory art therapies, psychological techniques, etc., as either key terms or keywords, with publication types including randomized controlled trial, controlled clinical trial, randomized, etc., published from inception (detailed retrievals are in [S4](#)) to April 10th.

Study Screening and Selection

According to the predefined inclusion criteria, two authors (H.C. and S.W.) separately reviewed the list of papers retrieved through preliminary screening titles and abstracts and full text with Endnote X7 to decide which could be included. Any controversial points were resolved with discussion after an independent review of the list of papers by another author (P.Z.).

Data Extraction and Management

Two authors (Y.W. and X.W.) separately extracted demographic data (country, diagnosis, criterion, comorbidity, outcome, sample size, age, sex, arm, treatment location, level of education, occupational status, marital status, and special or common population), and attempted to obtain the unpublished information necessary for the analysis from the original author by email. If missing information could not be provided, partial publication data were not considered. Studies excluded due to missing data were discussed with regard to their main characteristics to exclude possible biases.

Risk of Bias Assessment

Three authors (T.P. and Z.C. and P. Z.) separately assessed the quality of all reports using the Cochrane risk-of-bias tool for randomized trials (RoB)²⁷ to evaluate study methodological rigor with low, high, or unclear risk of bias (ROB) ratings for each domain. If there were conflicts, a fourth author provided guidance (L.L.) for consensus. To assess small-study effects, funnel plots for meta-analyses including at least 10 trials of varying sizes were planned (when available).

GRADE Quality Assessment of Evidence

The evaluation system GRADE (Grade of Recommendations Assessment, Development and Evaluation) was used to estimate the quality of direct, indirect, and network evidence. The direct evidence effect value and 95% CI are derived from the pairwise comparison results, and the indirect evidence effect value and 95% CI are derived from the node-splitting method. The network evidence comes from the meta-analysis results after fitting the consistency model.

Data Analysis Plan

Measures of Treatment Effect

Three main continuous variables were analyzed, in which PDA used the weighted mean difference (WMD) as the effect size (ES); Cohen's *d* method²⁸ was used to eliminate the influence of nonuniform dimensions of DDD and craving change. The closest estimation points to the post-last-treatment were considered. The ES of PDA was computed so that a positive value indicated a favorable outcome (ie, abstinence improvement), while changes in DDD and in craving were computed so that a negative value indicated a favorable outcome (ie, reduction of alcohol consumption and craving). Data based on the intention-to-treat (ITT) sample or modified sample were preferred over data based on completers for all analyses.

Pairwise Meta-Analysis

Direct pairwise meta-analysis (DMA) was conducted by Review Manager Version 5.0. for continuous outcomes. The MD was used to assess the effects on PDA of treatment and standardized mean difference (SMD) was used to assess the effects on DDD and craving change. The percentage of variability across trials was estimated with the I^2 statistic if attributable to heterogeneity beyond chance, which was deemed significant when $P < 0.05$ or $I^2 > 50\%$. The random-effects model was also considered, although the data were pooled with the fixed-effects model to ensure model robustness in the case of significant heterogeneity.

Network Meta-Analysis

Frequentist NMA²⁹ was conducted using Stata 14 taking all indirect comparisons into account. The agreement between direct and indirect evidence was assessed using a node-splitting analysis to test consistency.^{30,31} For any group of interventions included in the closed loop, the results were categorized into direct and indirect comparisons, and the difference was calculated and tested for statistical significance. If $P > 0.05$, they exhibit consistency; otherwise

inconsistency. If there was no inconsistency, a consistency model to show which psychotherapy was the most effective was used to produce rank probability plots, data expressed in form of MD or SMD with 95% CI. When there is inconsistency, the source will be discussed. If inconsistency could not be explained, the indirect evidence is unreliable.

Additional Analysis

This study supplemented a network comparison of intervention compliance to assess the patient's ability to adhere to a specific intervention, using the risk ratio (RR) as the ES. Separate meta-analyses by intervention type (psychotherapies alone or combined) or time point (short-, medium-, and long-term) were planned to assess the robustness of the results; sensitivity analyses were planned that excluded studies with high ROBIs; however, these were not completed owing to sparsity of data.

Results

Search results

The search produced 12,937 papers after 3728 duplicates were removed, of which 12,313 were excluded after preliminary screening. After the full-text screening, data were included from 34 independent studies ([Table S5](#)) for the qualitative systematic review of the 624 papers in the remaining pool ([Figure 1](#)).

Study Characteristics

The data pool for systematic analysis included 2646 individuals (34 RCTs) and for loop included 1928 (23 RCTs), covering: 9 countries and regions; 1981 males, 896 females and 1 transgender; 895 unmarried; 768 unemployed; 1910 outpatients. The mean age was 44.48 ± 11.28 years and the mean education years was 13.61 ± 3.00 years. The psychotherapies (used alone) involved CBT, MT, CT, Supportive psychotherapy (SP), Twelve-step facilitation (TSF), MET, CBM, Affect regulation training (ART), Exposure therapy (ET), Relapse prevention (RP), Mindfulness-oriented therapy (MOT), Relaxation therapy (RT), Brief counseling (BC), and Visual Short-Time Neurofeedback (VSTN), while psychotherapies (combination) involved naltrexone + CBT, naltrexone + MET, naltrexone + BC, fluoxetine + CBT, naltrexone + ET, sertraline + CBT, baclofen + CBT, MET + CT, MT + RP, TSF + CT, CBT + ET, and CBT + SP (details in [Figure S5](#) and [Table S5](#)). The common control treatments are Treatment as usual (TAU), placebo (PLC), TAU + PLC, etc. The brief description of the psychotherapies in this study was listed in [S3](#).

Risk of Bias Within Studies

Briefly, as the [Supplementary File](#) presents, 14.71% of the included trials were considered low risk, 66.67% were considered unclear risk, and 20.59% were considered high risk ([Figure S6A](#)). The unclear ROBIs were mainly concentrated in the randomization, allocation concealment, and blinding to therapists and patients, while the high ROBIs existed from the implementation to the reporting stage ([Figure S6B](#), details listed in [Table S6](#)).

Pairwise Meta-Analysis

[Table S7](#) presents the results of the pairwise meta-analysis and heterogeneity estimates. CBT (MD 30.72, 95% CI 23.63 to 37.81, GRADE high certainty) and MT (8.83, 95% CI 0.30 to 11.36, high certainty) were more efficacious than TAU for PDA but were not pooled because of the single trials. TAU+SP was more efficacious than TAU alone for the change in DDD (pooled SMD -0.57 , 95% CI -0.91 to -0.24 , $I^2=0\%$, high certainty). No difference was found between other direct comparisons.

Network Geometry and Synthesis of Results

The ranking probabilities and surface under the cumulative ranking curve (SUCRA) values are presented in [Figure S8A–C](#) and [Table S8A–C](#) for the three following outcomes.

The results of PDA were available for 22 arms (780 participants), including all 12 active interventions and TAU ([Figure 2](#)). With TAU as reference, the top nine interventions most likely to be accepted were as follows: MET+CT (47.2%), CT (44.8%), CBT (36.6%), RT (25.9%), TSF+CT (24.8%), TAU+CBT (39.4%), MT+RP (43.6%), MT

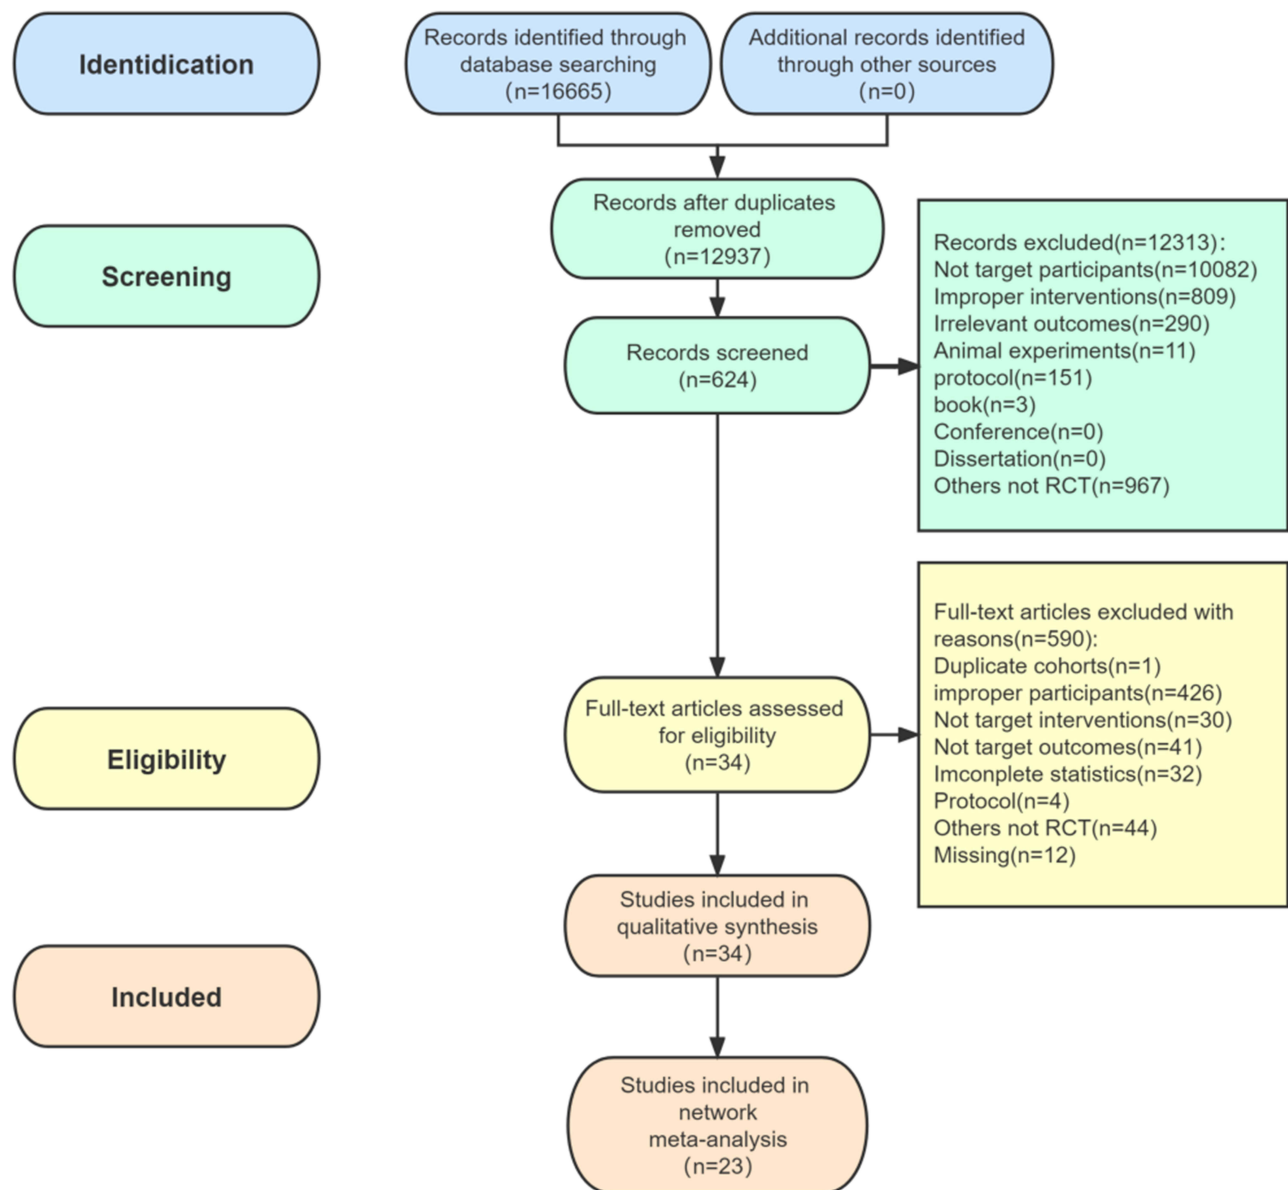

Figure 1 Flowchart of study selection.

(40.3%), and SP (34%), followed by TAU (50.7%). Among the SUCRA mean rankings, MET, MT, CT, TSF+CT, SP, RT, TAU+CBT, and MT+RP were ranked 1.9, 1.9, 3.0, 4.0, 4.6, 6.8, 7.0, and 7.4, respectively. Among these interventions, MET (MD 35.44, 95% CI 11.78 to 59.09, GRADE high certainty), CT (28.89, 95% CI 13.42 to 44.36, moderate certainty), TSF+CT (25.64, 95% CI 0.44 to 50.83, low certainty), MET+CT (35.24, 95% CI 15.16 to 55.32, very low certainty) and SP (21.79, 95% CI 4.14 to 39.44, very low certainty) were significantly different compared with TAU. Further details were shown in [Figure 3](#) and [Table 1–4](#), and [Figure S9Aa–c](#).

In terms of changes in DDD, available for 28 treatment arms (1121 participants), all 11 active and 3 control interventions (naltrexone+TAU, TAU, TAU+PLC) were included ([Figure S10A](#)). The top four most likely to be accepted were naltrexone+MET (55.4%), naltrexone+CBT (37.8%), PLC+MET (16.5%), and PLC+CBT (18.7%). Among the SUCRA rankings, naltrexone+MET, sertraline+CBT, and naltrexone+CBT were ranked 2.6, 5.1, and 5.2, respectively. The results of the NMA indicate that no treatment showed a significantly better effect than TAU or TAU plus PLC on the change in DDD ([Figure S9Ba–c](#)), and (d)). All of the significant evidence from active intervention comparisons were with low certainty ([Figure S11B](#) and [Table S12A](#)).

Figure 2 Network plot of PDA.

Notes: The node size is proportional to the number of participants randomised to each treatment, while the line width is proportional to the number of RCTs comparing each pair of treatments.

For changes in craving, available for 12 treatment arms (259 participants), all 4 active interventions and 2 controls (TAU and TAU+PLC) were included ([Figure S10B](#)). TAU+PLC (67.5%) had the highest probability of being best accepted, followed by TAU+SP (44%) and TAU+CBT (40.6%). Among the SUCRA rankings, TAU+PLC, TAU+SP, TAU+CBT, CBT, and TAU+VSTN were ranked 1.4, 2.4, 2.8, 4.0, and 5.1, respectively, and TAU was the lowest (5.3). No treatment showed a significantly better effect than TAU or TAU plus PLC ([Figure S11C](#) and [Table S12B](#)). Other details were shown in [Figure S9Ca–d](#).

In addition, the compliance of the active interventions also did not show better evidence than TAU in [Figure 3](#) (12 articles included).

Inconsistency

No statistically significant inconsistency were provided by fitting the node-splitting model ($P = 0.053$ to 0.990) or the global inconsistency model (PDA: $P = 0.1688$, change of DDD: $P = 0.6312$, and change of craving: $P = 0.0532$). Details were listed in [S13](#).

Small-Study Effects

For the publication bias of these three outcome indicators, due to the big number of types of psychological intervention comparisons but the small number of studies in each type, although it can be seen from [S14](#) that both positive and

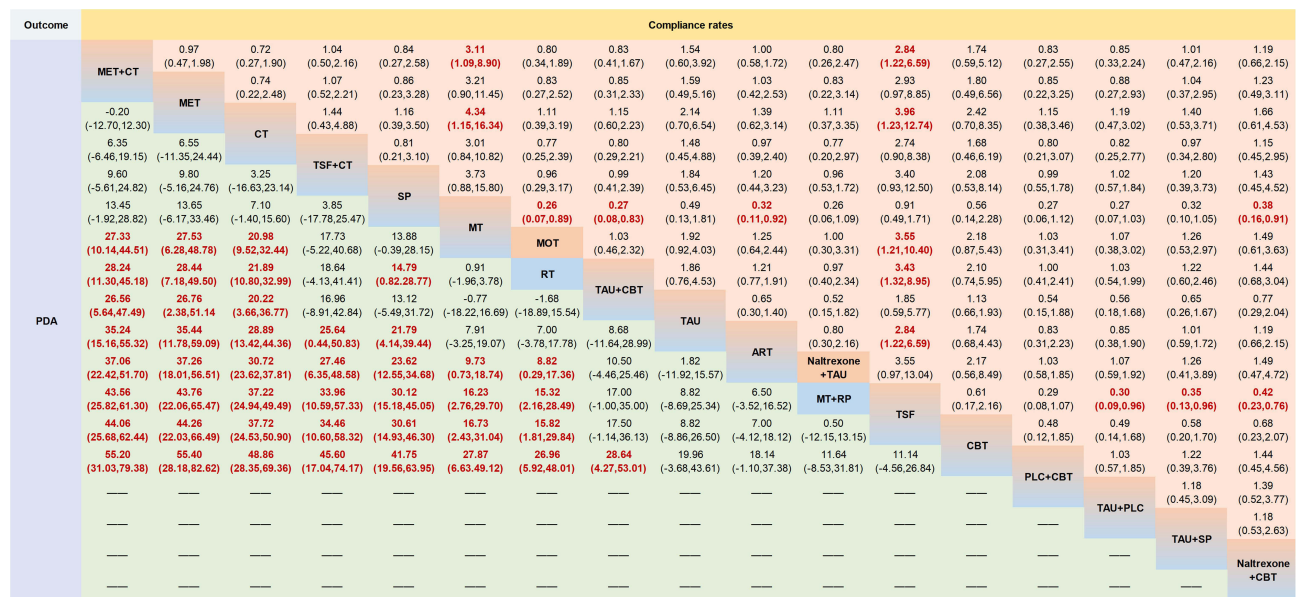

Figure 3 Network meta-analysis of PDA. Note: Effect sizes of PDA and compliance rates are represented by summary MDs and RRs respectively, and the 95% CIs of them. For the lower triangle (PDA), values greater than 0 favor the interventions in the corresponding column, whereas values lower than 0 favor the interventions in the corresponding row. For the upper triangle (compliance rates), collected from the included studies with clear information on treatment compliance (a total of 12 articles), values greater than 1 favor the interventions in the corresponding column, whereas values lower than 1 favor the interventions in the corresponding row.

negative reports occurred in the comparison network of PDA, it is still difficult to identify whether there is a small study effect in the comparative study of each pair of psychotherapies (Other details were in [S14](#)).

Discussion

Overview of Result

According to this systematic review and NMA, in terms of improving PDA, our findings provided further clarification about the abstinence efficacy of MET and CT protocols, which was significantly better than the efficacy of TAU with relatively higher evidence quality. Among the active interventions for PDA with high or moderate certainty comparisons, the four psychotherapies (MET, CT, MT, and RT) showed better effects than ART, CBT, and TSF, while MET and CT showed better effects than MT and RT, which suggests MET and CT as prior considerations in abstinence improvement. Additionally, TAU+SP was more efficacious than TAU for changing DDD in the high-quality direct comparison, although they had no other connection in the evidence network.

Comparison with Prior Studies

In the past, few systematic reviews have quantitatively presented the abstinence effect of MET on patients with AUD. Previous studies have shown that MET has an insignificant pooled ES in terms of alcohol consumption;¹³ however, regarding current network analysis, the potential for abstinence improvement of MET was revealed in this study. The latest RCT suggested that MI can reduce alcohol use by enhancing motivation and self-efficacy,³² additionally, helping patients resolve social stress is also one of the possible mechanisms for improving abstinence ability.³³

The results of some previous meta-analyses are similar to the network of CT in improving PDA in this study. The use of CT in the acute posttreatment of AD was strongly recommended in some guidelines.³⁴ There is an interaction causing a vicious circle between alcoholism and family relationships.³⁵ Therefore, detecting dysfunctional interaction patterns in family relationships contributes to obtaining alternative relationships. As a previous meta-analysis generally showed, CT is superior to more typical individual-based treatment for married or cohabiting to deal with AD.¹⁴

This study provided direct evidence of PDA evaluation for CBT rather than constituting network evidence. For improving PDA, it can be seen from the ranking probability that CBT is better than TAU, but there is no significant

Table I Estimates of Effect and Quality Ratings for Comparison of Psychotherapies for PDA (Significant Network Effect Between Active Therapy and TAU)

Comparison		Direct Evidence			Indirect Evidence			Network Meta-Analysis		
		SMD (95% CI)	MD (95% CI)	Quality of Evidence	SMD (95% CI)	MD (95% CI)	Quality of Evidence	SMD (95% CI)	MD (95% CI)	Quality of Evidence

difference in the network; this contradiction may be attributable to the non-transferability. The results in this study are similar to those in some recent related systematic reviews,¹⁰ which confirmed that CBT did not seem statistically better than other specific evidence-based therapies, revealing a moderate effect declining with time compared with TAU.^{10,11,36}

Moreover, network comparison also provides moderate-quality evidence for the superiority of ART to CBT, but the comparison lacks direct evidence. Highlighting the role of emotion as an important treatment goal of AD,³⁷ one study (study Walitzer 2015) in the loop showed that both ART and TSF significantly reduced alcohol-related consequences and anger-related thoughts as well as increased abstinence and self-confidence, thus their application was urged in AD.^{38–40}

This study also found that TAU+SP showed a significant effect on the change in DDD with high certainty of direct evidence. SP is rarely used independently, and its components are often used as a part of community conventional treatment or other psychological therapies.⁴¹ It can be operated face-to-face and can also provide remote support (like studies Agyapong 2012, Lucht 2014, O'Reilly 2019). Additionally, SP previously showed an effect on abstinence improvement in AUD,⁴² so it also needs to be treated as a kind of active and effective psychological intervention.

Strengths and Limitations of This Review

In terms of the strengths of this review, first, to ensure the designs of evidence-based evidence sources are rigorous and similar enough, this study only included relevant RCTs, focused on the dependent component in AUD, and excluded transient heavy drinking, and hazardous drinking implying risk prediction. Second, this study conducted GRADE evaluations for direct, indirect, and network meta-analyses, which have not been done previously.

Regarding the limitations, the completion and conviction of the conclusion may be weakened by the following aspects. First, some therapies included had few clinical studies and insufficient sample sizes for pooling or looping analyses.⁴³ Second, the small number of included studies and the lack of severity stratification of results in some of the studies did not facilitate the exploration of the association between severity and outcomes. Third, there was a lack of rigorous reports on randomization methods, allocation concealment, and control of implementation bias. Fourth, due to the influence of complex clinical factors and the limitations of the report content, the parameters of psychological intervention are indeed insufficient to support the impact on the outcomes by the duration, which needs to be further explored in clinical practice in the future. Furthermore, this article did not include multiple follow-up time points for analyses due to the limited outcome designs of the eligible studies.

Implications for Clinical Practice and Further Research

The advantages of MET and CT were indicated for abstinence in AUDs in this meta-analysis. They are two alternative psychotherapies on the primary care list of priorities to help persist in abstinence. However, at present, a comparison of rehabilitation strategies through MET for patients in different periods of AUDs remains to be explored. This study also shows some psychotherapies with significant efficacy but low or very low quality, requiring further research and investment. The inevitability that two or more psychotherapies are combined better than a certain therapy alone also needs to be further rigorously proven, and the stability of their long-term effects on AUD remains to be determined further.

Conclusion

This NMA provides evidence of psychotherapies for AUDs drinking control improvement and suggests that MET and CT may be the two preferred psychological options for primary care. Additionally, the preferred interventions for improving PDA and DDD are different. There is still a need for higher-quality RCTs to strengthen the evidence network and confirm the clinical benefits of other psychotherapies.

Neuropsychiatric Disease and Treatment**Dovepress****Publish your work in this journal**

Neuropsychiatric Disease and Treatment is an international, peer-reviewed journal of clinical therapeutics and pharmacology focusing on concise rapid reporting of clinical or pre-clinical studies on a range of neuropsychiatric and neurological disorders. This journal is indexed on PubMed Central, the 'PsycINFO' database and CAS, and is the official journal of The International Neuropsychiatric Association (INA). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
