Abstract: Carbon monoxide (CO) has attracted attention as a possible therapeutic agent for affecting anti-inflammatory and antioxidant activities. Previously, CO-bound hemoglobin vesicle (CO-HbV) was developed as a nanotechnology-based CO donor, and its safety profile and therapeutic potential as a clinically applicable carrier of CO were examined in vitro and in vivo. In the present study, the therapeutic efficacy of CO-HbV against severe acute pancreatitis was examined with secondary distal organ-injured model mice that were fed with a choline-deficient ethionine-supplemented diet. A CO-HbV treatment significantly reduced the mortality of the acute pancreatitis model mice compared to saline and HbV. Biochemical and histological evaluations clearly showed that CO-HbV suppressed acute pancreatitis by inhibiting the production of systemic proinflammatory cytokines, neutrophil infiltration, and oxidative injuries in pancreatic tissue. Interestingly, CO-HbV also diminished the subsequent damage to distal organs including liver, kidneys, and lungs. This could be due to the suppression of neutrophil infiltration into tissues and the subsequently enhanced oxidative injuries. In contrast, O₂-bound HbV, the inactive form of CO-HbV, was ineffective against both pancreatitis and distal organ injuries, confirming that CO was directly responsible for the protective effects of CO-HbV in acute pancreatitis. These findings suggest that CO-HbV has anti-inflammatory and antioxidant characteristics of CO and consequently exerts a superior protective effect against acute pancreatitis-induced multiorgan damage.

Keywords: acute pancreatitis, carbon monoxide, CDE diet, liposome, oxidative stress, inflammation

Introduction

Acute pancreatitis is a severe acute inflammatory disorder of the pancreas characterized by edema, acinar cell necrosis, and hemorrhage.¹ Although mild acute pancreatitis is not life-threatening, moderate-to-severe cases can lead to a rate of high mortality. Gabexate mesylate (GM), a protease inhibitor, is clinically used in some countries to treat acute pancreatitis based on evidence indicating that autodigestion by activated pancreatic enzymes is the initial event of acute pancreatitis.²⁻⁴ On the other hand, some governments, including the Food and Drug Administration (FDA), have not approved or recommended its clinical use^{5,6} because several clinical studies have shown that 1) the degree of hyperenzymemia is not a reliable predictor of the severity and final outcome of the disease and 2) GM has little or no benefit in case of acute pancreatitis patients.⁷⁻⁹ In addition to the release of digestive enzymes into the pancreatic

interstitium, the production of inflammatory cytokines and their release are also associated with the progression of severe acute pancreatitis.¹⁰

According to the revised Atlanta classification system, damage occurs typically in multiple distal organs including the liver, lungs, and kidneys after the development of severe acute pancreatitis. Although the exact mechanisms responsible for this are not fully understood, an accumulating body of evidence suggests that inflammatory cytokines and oxidative stress play a critical role in the onset and progression of this complication in acute pancreatitis.^{11,12} These systemic responses, which are generally referred to as the systemic inflammatory response syndrome (SIRS), lead to the development of more severe diseases such as multiple organ dysfunction syndrome (MODS), multiple organ failure (MOF), and finally death. In fact, patients who develop persistent distal organ failure within the first few days of the disease are at an increased risk of death, and the mortality has been reported to be as high as 36%–50%.^{13–15} These findings suggest that an agent that combines both anti-inflammatory and antioxidative actions would be expected to rescue patients with both severe acute pancreatitis and secondary distal organ injuries.

Emerging evidence indicates that carbon monoxide (CO), a by-product of inducible heme oxygenase-1, can effectively regulate inflammation and oxidative stress.^{16–18} In fact, recent studies on the use of CO inhalation or CO-releasing molecules (CORMs) showed that exogenous CO may well serve as a possible clinically viable medical agent for the treatment of inflammation- and oxidative stress-related disorders. By using advanced nanotechnology, recently, CO-bound hemoglobin vesicles (CO-HbV), in which a concentrated CO-bound hemoglobin (Hb) solution is encapsulated in a phospholipid bilayer membrane (liposome), were developed as a new type of CO donor.¹⁹ CO-HbV can function as a CO releasing molecule as a CO donor, and it also functions as an oxygen carrier after releasing CO.²⁰ This unique property of HbV as a dual-gas carrier promises to prevent CO-induced respiratory failure. In fact, previously, the safety characteristics of CO-HbV were reported: no effect on hemodynamics and respiratory function, a high biocompatibility, a low toxicity, and a good metabolic performance.²¹ Moreover, CO-HbV was reported to have therapeutic potential for retarding the onset or progression of idiopathic pulmonary fibrosis and inflammatory bowel disease by its anti-inflammatory and antioxidative activities.^{19,21} These findings lead us to hypothesize that CO-HbV might be a possible therapeutic agent for the treatment of both acute pancreatitis and secondary multiorgan failures.

The purpose of this study was to evaluate the therapeutic effects of CO-HbV on severe acute pancreatitis and its

secondary distal organ damage by using a choline-deficient ethionine-supplemented (CDE) diet-induced acute pancreatitis mice model. In addition, whether the anti-inflammatory and antioxidative functions of CO contribute to the therapeutic effect of CO-HbV was also investigated.

Materials and methods

Chemicals

The experiment using human red blood cells to produce HbV was approved by the ethical committee of Nara Medical University. Outdated donated human red blood cells were provided by the Japanese Red Cross Society (Tokyo, Japan), and human Hb was purified through pasteurization and nanofiltration as previously reported.^{22–24} The 1,2-dipalmitoyl-*sn*-glycero-3-phosphatidylcholine (DPPC), cholesterol, and 1,5-*O*-dihexadecyl-*N*-succinyl-L-glutamate (DHSG) were purchased from Nippon Fine Chemical Co. Ltd. (Osaka, Japan). 1,2-Distearoyl-*sn*-glycero-3-phosphatidyl-ethanolamine-*N*-PEG₅₀₀₀ (DSPE-PEG) was purchased from NOF Corp. (Tokyo, Japan). All other chemicals were the highest grade commercially available chemicals, and all the solutions were prepared by using deionized water. O₂-bound HbV and CO-HbV were prepared according to the previously reported procedures.¹⁹ The lipid bilayer of both HbV and CO-HbV consisted of DPPC, cholesterol, and DHSG at a molar ratio of 5/4/0.9 and DSPE-PEG of 0.3 mol%. The average diameters of the HbV and CO-HbV particles used in this study were maintained at ~280 nm. The HbV and CO-HbV suspended in a physiological salt solution were at [Hb] = 10 g/dL and [lipid] = 9.0 g/dL. The carboxyl Hb rate in CO-HbV was ~100%, whereas that in O₂-bound HbV was <5%.

Production of CDE diet-induced acute pancreatitis mice

Maintenance of the mice and the experimental procedures performed on them were carried out in accordance with the National Institute of Health guidelines. All the animal experiments were reviewed and approved by the Animal Care and Use Committee of Kumamoto University (permit no: A 27-003) and Sojo University (permit no: 2014-P-018). Female BALB/cN mice (aged 5 weeks) were purchased from Kyudo Co., Ltd. (Saga, Japan). All the mice were housed in a room kept at 18°C–24°C and 40%–70% relative humidity, with a 12-h light/dark cycle, and allowed free access to food and drinking water. After a 24-h period of fasting, the mice were fed a CDE diet (MP Biomedicals, Solon, OH, USA; catalogue no: 960214) for 3 days (for the analysis of therapeutic efficacies) or for 5 days (for the 14-day mortality rate). Saline, HbV (1,000 mg Hb/kg), and

CO-HbV (1,000 mg Hb/kg) were administered via tail vein at 1 day after the beginning of CDE treatment. The mice were fed a standard rodent diet CE-2 (CLEA Japan, Inc., Tokyo, Japan) outside of the CDE diet period.

Plasma biochemical parameters

Blood samples were collected from the inferior vena cava at 3 days after the start of the CDE treatment. The blood samples were centrifuged (3,000 g; 10 min) and subsequently ultracentrifuged to remove HbV (50,000 g; 30 min) in order to obtain plasma samples for the analysis of plasma biochemical parameters and cytokine levels. All the plasma biochemical parameters (amylase, lipase, aspartate transaminase [AST], alanine transaminase [ALT], and blood urea nitrogen [BUN]) were analyzed by using Fuji DRI-CHEM 7000Z and DRI-CHEM slides (Fujifilm, Tokyo, Japan).

Histological and immunohistochemical analyses

After blood collection, organs (pancreas, liver, kidneys, and lung) harvested for a histological and immunohistochemical study. The organs were fixed in 10% phosphate-buffered formalin and were embedded in paraffin. The prepared tissues were cut into 4- μ m-thick sections. Hematoxylin and eosin (HE) staining for morphological analysis and immunostaining for nitrotyrosine (NO₂-Tyr) and myeloperoxidase (MPO) were performed as previously described.²⁵ The primary antibodies containing NO₂-Tyr (Millipore, Tokyo, Japan; catalogue no: AB5411) and MPO (Santa Cruz, CA, USA; catalogue no: sc-16128-R) were diluted 50-fold prior to use. The secondary antibodies for NO₂-Tyr and MPO were Alexa Fluor 546 goat anti-rabbit IgG (H + L) (1:200; Invitrogen™, Eugene, OR, USA; catalogue no: AB11010). Cells were also treated with 4',6-diamidino-2-phenylindole (DAPI; Dojin Chemical, Kumamoto, Japan). After the reaction, the slides were observed by using a microscope (Keyence Corp., BZ-8000, Osaka, Japan).

Quantification of tumor necrosis factor (TNF)- α and interleukin-1 β (IL-1 β)

The amounts of TNF- α and IL-1 β in the plasma sample were determined by using an enzyme-linked immunosorbent assay kit (Biolegend, San Diego, CA, USA) following the manufacturer's instructions.

Measurement of the lung wet-to-dry ratio

One leaf of the left lung, which was used for the calculation of wet-to-dry ratio, was placed in a microtube, weighed, dried

at 80°C for 48 h, and weighed again. The wet lung was divided by value for the mass of the dry lung, representing the wet–dry lung ratio and indicating the fraction of the wet lung weight comprised of water.

Statistics

All data were expressed as the mean \pm standard deviation. Statistical analyses for multiple comparisons in the study were determined by analysis of variance (one-way or two-way) followed by the Bonferroni analysis. For survival studies, log-rank test was used. A *P*-value <0.05 was considered significant.

Results

Therapeutic potential of CO-HbV on CDE diet-induced acute pancreatitis

Feeding mice a CDE diet is a well-established method for producing a model for severe pancreatitis with a high mortality.^{26,27} In the present study, after feeding the mice the CDE diet, they were given saline, HbV, or CO-HbV administration via the tail vein at 24 h after the start of CDE feeding, and survival was monitored for the first 14 days. As shown in Figure 1, 100% (10/10) of the saline-treated mice and 90% (9/10) of the HbV-treated mice died within 7 days, whereas the 14-day mortality of the CO-HbV-treated mice was 50% (5/10). This survival rate for the CO-HbV-treated mice was significantly higher than the corresponding values for both the saline- and HbV-treated mice (*P*<0.05). Remarkable increases in serum amylase and lipase levels were noted in the saline-treated mice and the HbV-treated mice 3 days

Figure 1 Effect of saline, HbV, and CO-HbV administration on mortality in CDE diet-induced acute pancreatitis mice.

Notes: Survival rates were monitored for 14 days after the start of the CDE diet. Saline, HbV (1,000 mg Hb/kg), and CO-HbV (1,000 mg Hb/kg) were administered via the tail vein at 1 day after the start of the CDE diet (arrow). The number of mice (n) in all group was 10. *P*=0.044, saline versus CO-HbV. *P*=0.035, HbV versus CO-HbV.

Abbreviations: CDE, choline-deficient ethionine-supplemented; CO-HbV, carbon monoxide-bound hemoglobin vesicle.

after the start of feeding the CDE diet (Figure 2A). However, the CO-HbV treatment significantly attenuated the levels of these pancreatic enzymes (Figure 2A). The protective effect of CO-HbV on pancreatitis was also confirmed by the histological examination of pancreas sections stained by HE in each group (Figure 2B). Although the interstitium of the CDE-fed saline-treated mice and HbV-treated mice is edematous, the changes were greatly reduced in the CDE-fed mice that were treated with CO-HbV. A large number of inflammatory cells infiltrated to the interstitium of the saline- and HbV-treated mice, but few inflammatory cells infiltrated to the interstitium of the CO-HbV-treated mice. Similarly, diffuse necrotic changes were found in the saline- and HbV-treated groups but scarcely found in the CO-HbV-treated mice. These results suggest that CO-HbV is effective against acute pancreatitis and that the release of CO from the CO-HbV is responsible for its actions.

Effect of CO-HbV on inflammation and oxidative stress in pancreatic tissues

Neutrophil infiltration is a hallmark of inflammation, and evidence has accumulated to indicate that neutrophils play a key role in the induction of acute pancreatitis.²⁸ Therefore, immunostaining of MPO, an enzyme that is present at relatively

high levels in neutrophil granulocytes, was performed to evaluate neutrophil infiltration in the pancreatic tissues in the CDE diet-induced acute pancreatitis mice model for each sample treatment. As shown in Figure 3A, the accumulation of MPO in pancreatic tissues of the acute pancreatitis mice that were treated with saline and HbV was much higher than that in the control mice, whereas the CO-HbV treatment markedly reduced the accumulation of MPO.

As neutrophils that release toxic substances, such as reactive oxygen species (ROS), cause tissue injury in the inflamed pancreas,²⁹ pancreatic tissues were subjected to immunostaining for NO₂-Tyr, an oxidation product derived from proteins. NO₂-Tyr was observed to have accumulated in the CDE-fed mice treated with saline and HbV, whereas the CO-HbV treatment suppressed the level of this oxidative stress marker (Figure 3B).

Effect of CO-HbV on systemic inflammation in CDE diet-induced acute pancreatitis

A CDE diet induces not only localized pancreatic damage but also distal organ injury associated with a systemic inflammatory response. Thus, the effect of CO-HbV on systemic inflammation was assessed by measuring proinflammatory

cytokine levels in the circulation. As a result, the CO-HbV treatment significantly decreased the levels of serum proinflammatory cytokines, $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ (Figure 4).

Therapeutic potential of CO-HbV on distal organ injury in CDE diet-induced acute pancreatitis

In order to investigate the effect of CO-HbV on distal organ injury in the CDE diet-induced acute pancreatitis mice, the liver, kidneys, and lungs as distal organs were focused because injuries to these organs are frequently found in patients with severe acute pancreatitis. The values of AST and

ALT, which reflect hepatic injury, were found to be higher in the saline- and HbV-treated mice than the corresponding values in the CO-HbV-treated mice (Figure 5A). Livers obtained from the saline- and HbV-treated mice exhibited extensive hepatic necrosis (Figure 5B). Furthermore, immunostaining the liver sections for MPO and $\text{NO}_2\text{-Tyr}$ showed that the CO-HbV treatment suppressed the accumulation of MPO and subsequent oxidative injury in the liver compared to the saline and HbV treatments (Figure 5C and D).

In the kidneys, it was observed that the CO-HbV treatment attenuated the extent of renal injury in CDE-fed mice based on the results of serum BUN levels (Figure 6A)

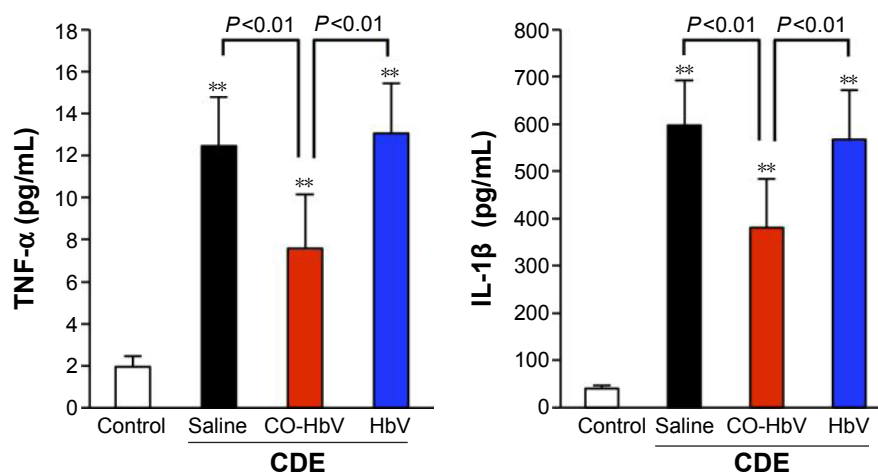

Figure 4 Effect of saline, HbV, and CO-HbV administration on systemic inflammation in CDE diet-induced acute pancreatitis mice.

and histological evaluations (Figure 6B). In the lungs, the wet-to-dry ratio, which reflects edema, in the CO-HbV-treated mice was significantly lower than that in saline- and HbV-treated mice (Figure 7A). In addition, HE staining of lung sections exhibited alveolar membrane thickening in both the saline- and HbV-treated mice, but it was suppressed in CO-HbV-treated mice (Figure 7B). Similar to the immunostaining of liver sections, as shown in Figure 5C and D, the CO-HbV treatment clearly suppressed the accumulation of MPO and NO₂-Tyr in the kidneys and lungs compared to the saline and HbV treatments (Figures 6C and D and 7C and D).

Discussion

Acute pancreatitis is one of the most frequent gastrointestinal diseases, and mild cases require 2- to 5-day hospital stays. In more severe cases, such as the development of complications including MOF, hospitalization can be prolonged considerably, with a much cost.³⁰ Although worldwide guidelines have been established for managing acute pancreatitis, including rehydration, early nutrition, acceptable analgesia, oxygenation, and the use of antibiotics, when infections are confirmed,^{31–34} there is no recommended drug protocol for preventing the progression of pancreatitis itself. Therefore,

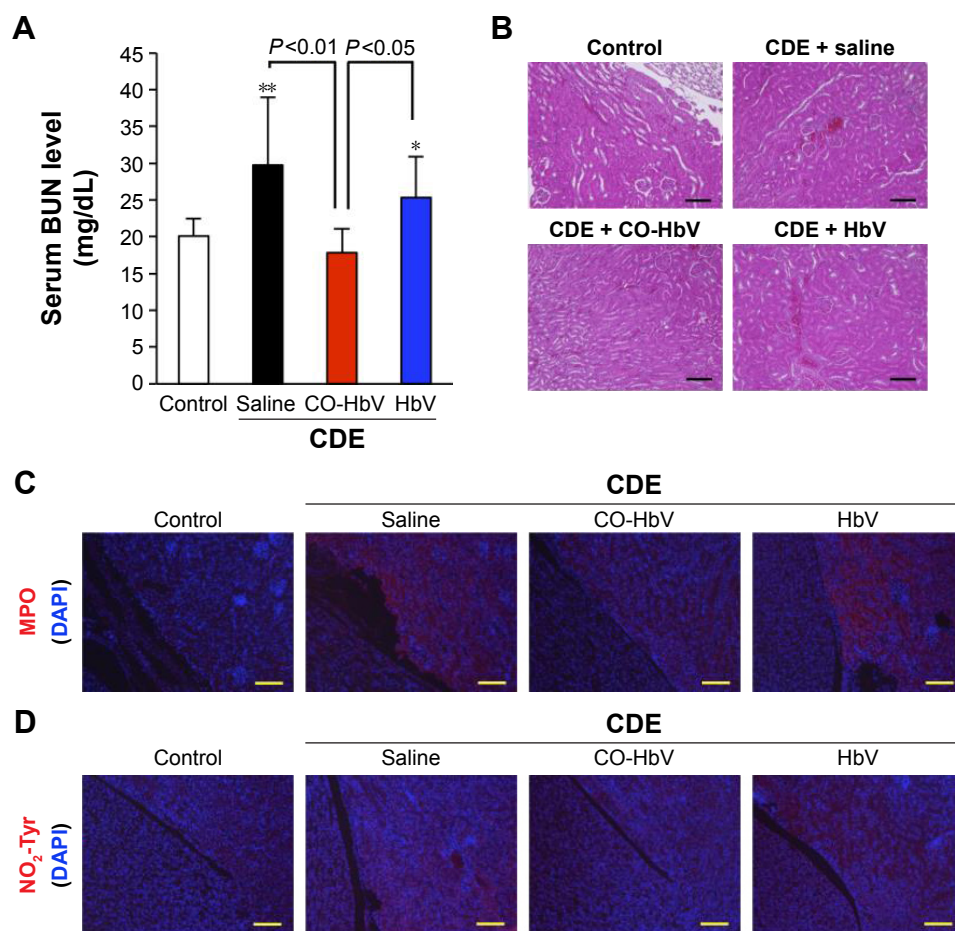

Figure 6 Evaluation of renal injury and immunological staining of kidney sections after the administration of saline, HbV, and CO-HbV to CDE diet-induced acute pancreatitis mice.

developing safe and effective therapeutics that are able to protect both the pancreas and distal organs under conditions of severe pancreatitis would be highly desirable. The findings reported in the present study strongly indicate that CO-HbV significantly improves the survival rate of mice with CDE diet-induced acute pancreatitis through the reduction of severe acute pancreatitis and by reducing the extent of secondary distal organ injuries (Figures 1 and 2). Clinical studies have clarified that a severe condition of acute pancreatitis is associated with a mortality reaching 30%, even when the recommended medical and surgical therapies are performed.³⁴ Based on the present findings, it appears that CO-HbV represents a novel and effective therapeutic strategy for reducing severe pancreatitis in patients and subsequently improves their mortality.

It is well known that ROS play an essential role in the progression of acute pancreatitis³⁵⁻³⁷ because it directly interacts with biological molecules in the body and impairs their function. Although ROS are produced by multiple pathways in

pathological conditions, neutrophils are important ROS generators and are responsible for local tissue damage.³⁸ Cunha et al previously reported that a CO donor (dimanganese decacarbonyl) inhibited the adhesion and migration of the neutrophils during the inflammatory response.^{39,40} In this study, it was found that the administration of CO-HbV attenuated MPO accumulation, which is frequently used to estimate the extent of accumulation of tissue neutrophils in inflamed tissue,^{41,42} in pancreatic tissue under conditions of severe acute pancreatitis (Figure 3A). Furthermore, corresponding to MPO accumulation, CO-HbV efficiently inhibited the accumulation of NO₂-Tyr, a marker of oxidative stress for proteins (Figure 3B). Thus, it appears that CO-HbV inhibits the infiltration of neutrophils and subsequent ROS injuries in pancreatic tissue, resulting in the suppression for the progression of acute pancreatitis.

Proinflammatory cytokines, such as TNF- α and IL-1 β , are mainly produced and released during severe acute pancreatitis and are thought to significantly contribute to

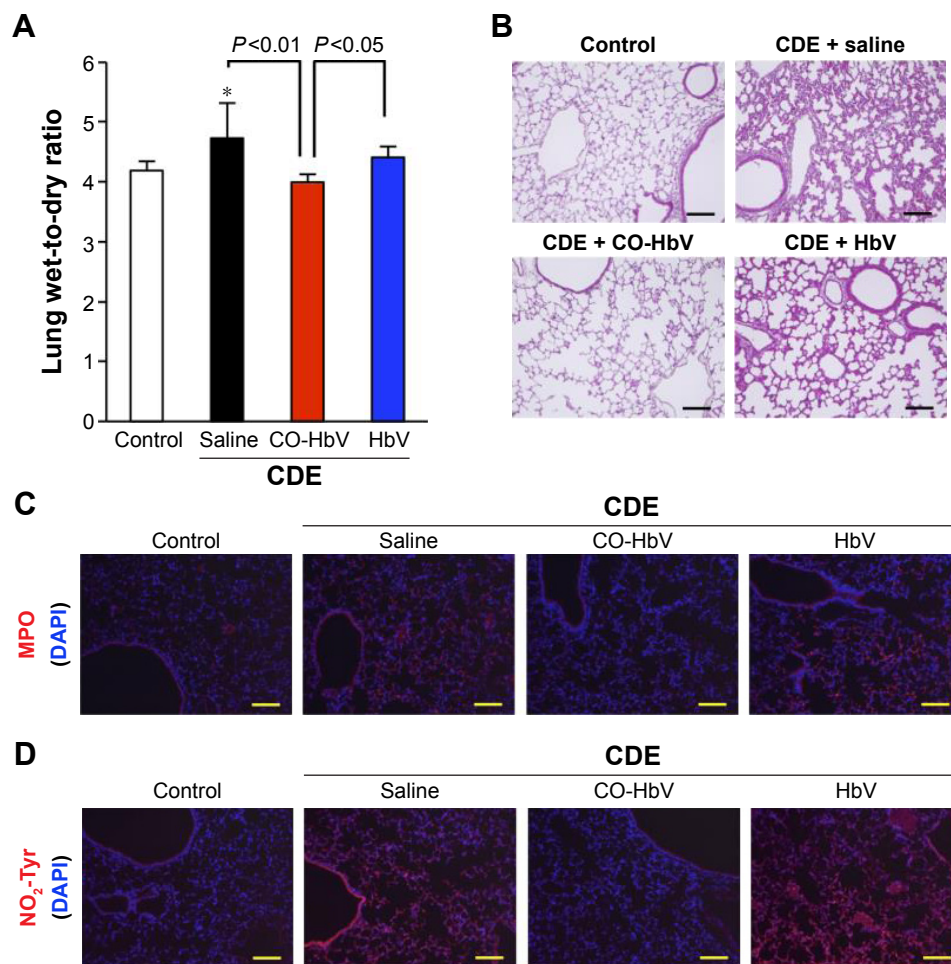

Figure 7 Evaluation of lung injury and immunological staining of lung sections after the administration of saline, HbV, and CO-HbV to CDE diet-induced acute pancreatitis mice.

Scale bars represent 100 μ m.

Abbreviations: CDE, choline-deficient ethionine-supplemented; CO-HbV, carbon monoxide-bound hemoglobin vesicle; DAPI, 4',6-diamidino-2-phenylindole; HE, hematoxylin and eosin; MPO, myeloperoxidase; NO₂-Tyr, nitrotyrosine.

the onset and progression of pancreatitis.^{43,44} For example, a marked attenuation of the severity of acute pancreatitis is observed when receptors for TNF- α and IL-1 β are blocked, and the mortality is dramatically reduced in TNF- α and IL-1 β knockout mice after the development of severe acute pancreatitis.^{45–47} Moreover, anti-cytokine therapies against TNF- α and IL-1 β showed protective effects in experimental animal models with severe acute pancreatitis.⁴⁸ Since the serum levels of TNF- α and IL-1 β during the course of severe acute pancreatitis were decreased by a CO-HbV treatment (Figure 4), the therapeutic effect of CO-HbV could be modulated by the production of systemic cytokines.

In order to emphasize this, CO-HbV was found to comprehensively ameliorate not only pancreatic injury but also secondary distal organ damage, including liver, kidneys, and lungs in the present acute pancreatitis model. This implies that CO-HbV could suppress the SIRS and MODS that accompany

severe acute pancreatitis (Figures 5–7). Disease-related systemic responses, such as SIRS, are mediated by different inflammatory cytokines that are released during the course of primary organ injury. In particular, TNF- α and IL-1 β play a pivotal role in the development of the SIRS and the subsequent distal organ failures in cases of severe acute pancreatitis.⁴⁴ In the present study, CO-HbV was found to effectively inhibit TNF- α and IL-1 β production in the circulation (Figure 4). In addition, neutrophils are also considered to play an important role in the onset and development of secondary distal organ damage in various diseases.^{49–51} As described previously, the infiltration of neutrophils into tissues causes substantial oxidative injury to distal organs. Similar to the pancreas, CO-HbV suppressed neutrophil infiltration and subsequent ROS injuries in the liver, kidneys, and lungs of CDE mice (Figures 5–7) as judged by immunostaining for MPO and NO₂-Tyr. These findings indicate that both the anti-inflammatory and antioxidative

activities of CO-HbV not only play an important role in its protective effects against acute pancreatitis but also mediate multiple distal organ injuries.

In the present study, it was determined that CO directly contributed to the therapeutic effects of CO-HbV on both acute pancreatitis and its complications because HbV that was loaded with oxygen was ineffective. This indicates that HbV has the capacity to carry and release CO in vivo. Accumulating evidence has confirmed the safety and usefulness of HbV as an oxygen carrier such as its biological compatibility,²² the absence of toxicity,²³ no accumulation in the body,^{52,53} and ability to transport oxygen.^{54,55} These beneficial properties of HbV can be retained, even in the form of CO-HbV.²¹ Moreover, HbV has been reported to have a good retention in the blood circulation of cynomolgus monkeys,⁵⁶ and the half-life of HbV in humans was estimated to be ~3–4 days.⁵⁷ Consequently, HbV is a promising, safe gas carrier for both CO and oxygen with long-acting properties. For the clinical application of CO-HbV, the characterization of CO release from CO-HbV is an important issue. Thus, further investigation regarding this pharmacokinetic study will be necessary to develop a comprehensive understanding of the effect of CO-HbV on acute pancreatitis.

Conclusion

The findings of the present study show that 1) CO-HbV can significantly decrease mortality and prevent both pancreatic damage and severe complications (multiple organ injuries) via the anti-inflammatory and antioxidant activities of CO and that 2) CO-HbV functions as a CO donor, suggesting that CO-HbV could be a promising nanotechnology-based CO donor and has the potential for use as a therapy not only for acute pancreatitis but also for a wide range of ROS and inflammation-related diseases.

International Journal of Nanomedicine

Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Submit your manuscript here: <http://www.dovepress.com/international-journal-of-nanomedicine-journal>

Dovepress

Journal Citation Reports/Science Edition, EMBASE, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
