Background: Oral halitosis, unpleasant or offensive odor to others, has become a major health concern among the general population, ranking the third most common reason for seeking a dentist behind dental caries and periodontal disease. Even though there have been repeated cases of halitosis in Ethiopia, there is no documented evidence.

Objective: The purpose of this study was to determine the prevalence of halitosis in Northwest Ethiopia and to examine the relationship between halitosis and sociodemographic factors, oral habits, and health practices.

Methods: From December 2019 to March 30, 2020, a hospital-based cross-sectional study was conducted. A systematic random sampling method was used to select study participants. Following informed consent, sociodemographic characteristics were collected using structured questionnaires, and two qualified dental surgeons performed the oral examination. The organoleptic test was used to assess the presence of halitosis.

Results: Six hundred sixty-one people took part in the study, with a mean age of 30.0 ± 14.76 years. The prevalence of oral halitosis was 44.2% (95% CI: 40.39–47.96) among the study participants. Participants with no formal education were more prone to oral halitosis. Oral halitosis was common in students (18.5%), low-income individuals (22.2%), rural residents (12.3%), mouth breathers (19.1%), and participants with poor oral hygiene practices (15.3%). Independent factors of halitosis included rural residency (AOR=1.40, 95% CI: 1.18, 1.67), low economic status (AOR=1.81, 95% CI: 1.06, 3.09), poor tooth brushing habit (AOR=1.85 (1.31, 2.61), smoking (AOR=2.69 (1.39, 5.21) and dental caries (AOR=8.74 (5.57, 13.71).

Conclusion: The prevalence of oral halitosis was 44.2% among the study participants. Rural residency, low monthly income, poor tooth-brushing habit, smoking, and dental caries were independent factors of halitosis.

Keywords: bad breath, oral halitosis, prevalence, oral malodor, Northwest Ethiopia

Background

Halitosis, also known as malodor, is a worldwide public health issue.¹ It is a foul or offensive odor emitted from a person's mouth.² The most common volatile molecules that cause halitosis are sulfur compounds, amines, nitrogen-containing compounds, alcohols, short-chain fatty acids, aliphatic compounds, and ketones are the common volatile compounds that cause halitosis.^{3,4} Etiologically halitosis is classified into physiologic (type 0), oral (type 1), airway (type 2), gastroesophageal (type 3), blood-born (type 4) and subjective (type 5).^{5,6}

Halitosis is reported to be the third most common reason for visiting a dentist, trailing only dental caries and periodontal disease.^{7,8} The prevalence of halitosis among adults worldwide ranged from 22% to 50%.⁹ Halitosis has a social impact on those who suffer from it, affecting their normal daily activities such as social and professional relationships, as well as communication.¹⁰ Furthermore, it has an impact on an individual's confidence, self-esteem, reduces employment, and overall quality of life.^{10,11} The psychological effect of halitosis forced individuals to excessive use of chewing gums, mouthwashes, or medications to mask the odor and find a solution to this distressing problem.¹²

Halitosis has a multifactorial etiology, but the main factor is the decomposition of organic matter by proteolytic anaerobic bacteria.¹³ Poor oral hygiene, misaligned tooth, fault restoration, wound infection, smoking, alcohol, some foods, dry mouth, stress, obesity, periodontal disease, ill-fitting denture, and upper respiratory tract infections were the commonly reported causes of halitosis were the common causes.^{13,14} In the general population, 80–85% of halitosis cases were caused by intraoral factors,^{13,15} with the remaining 10% caused by upper respiratory tract infections.^{16,17}

To date, there is a scarcity of data on the prevalence and associated factors of oral halitosis in Ethiopia. Therefore, this study aimed to determine the prevalence of oral halitosis and its associated factors in Northwest Ethiopia.

Patients and Methods

Setting

A hospital-based cross-sectional study was conducted at the University of Gondar Comprehensive specialized hospital dental clinic from December 1, 2019, to March 30, 2020. The hospital serves more than 7 million people in the catchment area. The dental clinic is one of the specialty centers in the University of Gondar comprehensive hospital, which has both outpatient and inpatient departments.

Study Participants

The source population included all patients who visited the University of Gondar comprehensive specialized hospital, while the study population included those who visited the dental clinic during the data collection period.

Exclusion Criteria

Participants who met the following criteria were excluded from the study.

- A patient with a dental emergency or who was critically ill
- A history of tooth extraction within a week
- Patients who refused to sign a consent form
- Pregnant women
- Participants fasted from the previous midnight until the time of evaluation
- Individuals with sore throat and sinusitis, neurological, psychiatric, or behavioral disorders

Sampling Technique and Procedures

The single population proportion formula was used to calculate the sample size. Assuming a prevalence of 50% (no previous study in Ethiopia), a margin of error of 4%, and a non-response rate of 10%, the final sample size was 661.

Sampling Procedure

A systematic random sampling method was employed to select the study subjects. The sampling interval (K) was calculated by dividing the predicted number of participants per month by the sample size. A lottery method was used to determine the first study participant and every fourth patient was included in the study (K=4) until the desired sample size was achieved.

Data Collection

The questionnaire used in this study was adapted from previous studies.^{18–20} The questionnaire includes information about sociodemographic characteristics (such as sex, age, marital status, occupation, residency, and monthly income), oral hygiene practice, dietary habits, smoking history, and systemic disease. Moreover, the intraoral examination includes information about dentition status, periodontal condition, and occlusal relationship.

The study included questionnaire administration and clinical oral examination. Data on the self-administered questionnaire was collected in the waiting area of the dental clinic before the intraoral examination.

Oral Examination/Organoleptic Test

Two calibrated dentists performed the intraoral examination and organoleptic test. The magnitude of the odor was graded on a scale of 0 to 5 (0: no odor, 1: barely noticeable, 2: slight but noticeable, 3: moderate, 4: strong, and 5: extremely strong).^{21,22} To reduce the procedures, the two dentists did the organoleptic test at the same time; nevertheless, neither of them was aware of the other examiner the assessment. Participants with an organoleptic test score of ≥ 2 were considered as having oral halitosis.^{23–25} The organoleptic test was performed 2 hours

after breakfast to avoid false results caused by fasting and certain diets that alter the odor of the oral cavity.²⁶ There was a 5-minute break between each examination to standardize the clinical examination and avoid adaptation.

Quality Assurance

To ensure the study's quality, a pilot test was performed on 70 individuals who shared the same socio-demographic characteristics as the study's participants. Some amendments were made to the prepared questionnaire based on the results of the pilot test. For five days, data collectors were trained on research ethics, study objectives, data confidentiality, and consent.

Data Analysis

Data were cleaned, coded, and entered using the Epi-Info version 7. SPSS software (version 26) was used to analyze the data. Categorical variables were presented using frequencies and percentages. Binary logistic regression models were used to

evaluate the presence of a statistical association between independent factors and halitosis. Study variables with a P-value of ≤ 0.2 were entered into the multivariable model to control the possible confounders. The level of significance was set at 5%.

Ethical Consideration

The Institutional Review Board (IRB) of the University of Gondar approved the study (V/P/RCS/05/149/2019). Written consent was obtained from each study participant, and written assent was taken from parents or legal guardians for under 18 years children. The authors tried to minimize the study participant's confidentiality by avoiding personal identifiers.

Results

Sociodemographic Characteristics of the Study Participants

Six hundred sixty-one participants were involved in the study with a response rate of 100%. The mean age of the study participants was 30.0 ± 14.766 (SD) years with a median age

Table 1 The Prevalence of Halitosis According to the Socio-Demographic Characteristics of the Study Participants

Socio-Demographic Characteristics		Halitosis			P-value
		Yes	No	Total	
Sex	Male	143 (21.6%)	195 (29.5%)	338 (51.1%)	0.347

Monthly income	< 1000 ETB	147 (22.2%)	152 (23.0%)	299 (45.2%)	0.000
	1000–2500 ETB	92 (13.9%)	96 (14.5%)	188 (28.4%)	
	≥ 2501 ETB	53 (8.0%)	121 (18.3%)	174 (26.3%)	

of 28.0. The majority of the study participants (72.9%) were within 12–34 years. More than 1/3rd of the study participants attended college/university and 3/4th of the study participants were urban residents (Table 1).

The Prevalence of Halitosis Among the Study Participants

The prevalence of oral halitosis was 44.2% among the study participants (95% CI: 40.39–0.4796). Halitosis was found in 1/3rd (31.5%) of participants aged 12 to 34 years. The prevalence was relatively high in rural residents (22.3%), and participants with low monthly income

(22.2%) (Table 1). Furthermore, 55.2% of participants with poor tooth brushing habits had oral halitosis. Oral halitosis was common in mouth breathers (58.6%), smokers (66.7%), and patients with dental caries (81.3%) (Table 2).

Factors Associated with Halitosis Among the Study Participants

Variables, which had a significant association in the bivariate analysis (age, educational status, occupation, residency, monthly income, tooth brushing habits, smoking, and dental caries), entered into the multivariate logistic regression

Table 2 Prevalence of Halitosis Among the Study Participant According to the Oral Health Practice, Oral Habits and Dietary Factors

Risk Factors		Halitosis		Total	P-value
		Yes	No		
A habit of tooth brushing	Yes	191 (28.9%)	287 (43.4%)	478 (72.3%)	0.000
	No	101 (15.3%)	82 (12.4%)	183 (27.7%)

Dental caries	Yes	122 (18.5%)	28 (4.2%)	150 (22.7%)	0.000
	No	170 (25.7%)	341 (51.6%)	511 (77.3%)	
Malocclusion	Yes	35 (5.3%)	0 (0.0%)	35 (5.3%)	0.007
	No	257 (38.9%)	369 (55.8%)	626 (94.7%)	

model as independent variables for the outcome of halitosis. The analysis showed that residency, monthly income, tooth-brushing habits, smoking, and dental caries were identified as independently associated with halitosis (Table 3).

Discussion

The prevalence of halitosis was found to be 44.2% (95% CI: 40.39–0.4796) which is consistent with a study done in Saudi Arabia (42.1%).²⁷ However, this result is higher than a study done in Kuwait (23.3%)²⁹ and lower compared with studies done in Pakistan (75.1%)³⁰ and Brazil

(63%).³¹ The difference might be due to variation in the study population and socio-demographic variation between the countries.

The present study found that oral halitosis was high in smokers where smokers were 2.69 times at risk of developing halitosis than nonsmokers (AOR= 2.69, 95% CI: 1.39, 5.21) which is consistent with previous studies.^{29,33,34} This might be due to some volatile compounds in cigarettes.³⁵ Furthermore, participants with dental caries were 8.74 times more likely to develop halitosis than non-carious patients which is similar to a study done in Brazil (AOR=3.8, 95% CI: 1.6–9.2).³⁶ The high prevalence of halitosis might be due

Table 3 Logistic Regression Analysis to Show the Relation Between Halitosis and Associated Factors Among Participants Involved in the Study

Variables		Halitosis		AOR
		Yes	No	
Marital status	Single	137 (20.7%)	170 (25.7%)	2.88(0.84,9.03)
	Married	149 (22.5%)	178 (26.9%)	4.41(2.16,17.10)
	Divorced	6 (0.9%)	21 (3.2%)	1

	No	252 (38.1%)	348 (52.6%)	1
Dental caries	Yes	122 (18.5%)	28 (4.2%)	8.74(5.57,13.71)
	No	170 (25.7%)	341 (51.6%)	1

to the presence of poor oral hygiene practice and calculus accumulation in patients with dental caries.

On analysis of socioeconomic variables, a statistically significant association was found between rural residency, low monthly income, and oral halitosis. Rural residents were two times at risk of developing halitosis than urban residents (AOR=1.94, 95% CI: 1.33, 2.82) which corresponds with a study done in Korea.³⁷ This might be due to low knowledge of oral health, and poor oral hygiene practice among rural residents. Besides, participants with low monthly income were 2.21 times at risk of developing halitosis (AOR=2.21, 95% CI: 1.29,3.79) which is similar to a study done in Korea (AOR=1.85).³⁷

Lack of oral hygiene practice, including, flossing, and use of mouthwash, has been connected to oral halitosis. In this study, participants with poor tooth brushing practice were 1.85 times at risk of affected by oral halitosis (AOR=1.85 (1.31, 2.61)).

Strengths and Limitations

The present study had some limitations; first, the study did not use objective measurements of halitosis using a portable VSC detector, halimeter, or gas chromatography. Due to this, some false positives/negatives might be reported. Second, even if we used systematic random sampling participants with self-reported halitosis might exclude themselves from the study. Third, the study is a single site and hospital-based study, which will not represent the whole society of the area. The study also evaluated only oral halitosis.

Conclusion

The prevalence of oral halitosis in the study participants was 44.2%. Rural residency, low monthly income, poor tooth-brushing habit, smoking, and dental caries were independent factors of halitosis.

Data Sharing Statement

All the data used during the analysis were no publicly available due to the agreement between the authors and the IRB of the university, but data are available from the corresponding author on reasonable request.

Ethical Approval and Consent to Participate

Ethical approval was obtained from the institutional review board of the University of Gondar. The study complied with the Declaration of Helsinki Ethical Principles for Medical Research. Written informed consent was taken from each participant and data collection was done after they signed for the consent. Moreover, informed consent was taken from parents or legal guardians for 12-18 years old.

Acknowledgment

We would thank the University of Gondar for the ethical clearance, and the dental staff for their valuable support for the project. Furthermore, we would like to acknowledge all the participants for their contribution by being part of the study.

Author Contributions

All authors made a significant contribution to the work reported, whether that is in the conception, study design, execution, acquisition of data, analysis and interpretation, or in all these areas; took part in drafting, revising or critically reviewing the article; gave final approval of the version to be published; have agreed on the journal to which the article has been submitted; and agree to be accountable for all aspects of the work.

Clinical, Cosmetic and Investigational Dentistry

Publish your work in this journal

Clinical, Cosmetic and Investigational Dentistry is an international, peer-reviewed, open access, online journal focusing on the latest clinical and experimental research in dentistry with specific emphasis on cosmetic interventions. Innovative developments in dental materials, techniques and devices that improve outcomes and patient

satisfaction and preference will be highlighted. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
