Objective: This study aimed to reveal the potential function of methylenetetrahydrofolate dehydrogenase 2 (MTHFD2) and emphasized its importance in brain low-grade glioma (LGG).

Methods: We firstly explored the differential expression of MTHFD2 mRNA in LGG and normal tissues, followed by correlation analysis of MTHFD2 mRNA expression with patient's clinical characteristics. MTHFD2 protein expression in LGG and subcellular location were also evaluated. Then, survival analysis was performed to reveal the influence of MTHFD2 expression on the overall survival of patients, and Cox regression analysis was applied to predict the prognostic factor for overall survival of LGG. Finally, we performed functional analysis to reveal potential MTHFD2-associated pathways involved in LGG.

Results: We found that MTHFD2 was highly expressed in LGG patients ($P < 0.05$), and MTHFD2 expression was related to patient's age and IDH mutation status (all $P < 0.05$). MTHFD2 protein was mainly localized to the mitochondria. Survival analysis showed that high expression of MTHFD2 desirably improved the prognosis of LGG patients ($P < 0.001$), especially for those patients with age ≥ 45 years ($P < 0.05$). But independent prognostic role of MTHFD2 in LGG was not observed. Pathway enrichment analysis indicated that MTHFD2 high expression significantly and positively participated in the pathway of one carbon pool by folate (all $P < 0.05$).

Conclusion: High expression of MTHFD2 was observed in LGG, which was favorable for the overall survival of LGG patients. Our results assumed that MTHFD2 high expression might play a pivotal role in LGG through positively regulating pathway of one carbon pool by folate.

Keywords: MTHFD2, low-grade glioma, high expression, prognosis

Introduction

Glioma is the most common malignant tumor in the central nervous system, accounting for 70% of brain cancers.¹ According to the latest statistic reports in China,² 101,600 new cases and 61,000 related deaths have appeared. The World Health Organization classified gliomas into grade 1 to grade 4 based on histology and clinical criteria.³ Brain low-grade gliomas (LGG), belonging to grade 2 tumor, accounted for 15–25% of all gliomas and included astrocytomas, oligoastrocytomas and oligodendrogliomas.⁴ LGG was relatively benign as well as slow-growing, and overall survival (OS) of children and adolescents with LGG exceeded 90% at 5 to 10 years.⁵ Despite growing slowly initially, essentially all LGG lesions eventually progress to high-grade glioma (HGG) (Grade 3/4).^{6,7} Approximately 50% of patients with LGGs

will experience malignant transformation within 5 years.⁸ Previous study has identified several diagnostic and prognostic signatures, such as PWP2, FGR and BMP2, which may be utilized as biomarkers for diagnosis and prognosis, and for development of a treatment strategy for LGG.⁹ It was of great significance that identification of potential therapeutic biomarker for LGG patients to improve their clinical outcome.

Methylenetetrahydrofolate dehydrogenase 2 (MTHFD2) is a mitochondrial enzyme involved in folate metabolism,¹⁰ as well as a bifunctional enzyme with methylene dehydrogenase and cyclohydrolase activities.¹¹ Growing evidence demonstrated the up-regulation of MTHFD2 in various cancers and its over-expression was associated with tumor cell proliferation.¹² Inhibition of MTHFD2 expression affected the proliferation of lung,¹³ breast¹⁴ and acute myeloid leukemia¹⁵ cancer cells. These studies also highlighted MTHFD2 as being a promising therapeutic target for cancer treatment. MTHFD2 was identified as the drug target to block breast cancer cell migration and invasion.¹⁶ Additionally, MTHFD2 has been suggested to play an important role and potentially be valuable in the prognosis and treatment of glioma.¹⁷ Furthermore, immunohistochemical validation revealed that MTHFD2 was positively expressed in diffuse LGG.¹⁸ Currently, it has been regarded as one of the candidate marker genes for tumor invasion, metastasis and poor prognosis.¹⁰ Despite the growing interest about MTHFD2 as a potential target in cancers, the potential function of this enzyme in LGG has not been defined.

The present study was aimed at revealing the potential role of MTHFD2 in LGG. We explored the MTHFD2 expression in LGG patients, assessed its influence on patient prognosis and revealed its prognostic value on overall survival. Finally, MTHFD2-associated pathway was explored to understand the potential mechanism involved in LGG.

Methods

MTHFD2 mRNA Expression Analysis

We firstly explored the mRNA expression profile of MTHFD2 across all tumor and normal tissues through Gepia database (<http://gepia.cancer-pku.cn/>). The differential expression of MTHFD2 mRNA in normal and LGG samples was also analyzed. Correlation analysis between MTHFD2 mRNA expression and patient's age, BRAF genetic status, tumor locations, primary or

recurrent tumor, and primary tumor that further progressed was performed using GSE60898 dataset, which was obtained from GEO database (<https://www.ncbi.nlm.nih.gov/geo/>). In addition, the effects of age, gender, tumor subtypes, IDH mutation status, pharmaceutical therapy, and radiation therapy on MTHFD2 expression was also explored using TCGA Lower Grade Glioma (LGG) cohort, which was obtained from UCSC Xena database (<https://xenabrowser.net/>). Due to the significance of MTHFD2 in brain cancer, we also explored the MTHFD2 mRNA expression in human brain by HPA database (<https://www.proteinatlas.org/>).

MTHFD2 Protein Expression

Furthermore, the protein expression of MTHFD2 in normal and LGG tissues was also evaluated in HPA. The subcellular location of MTHFD2 protein in cancer cells is determined by indirect immunofluorescence microscopy in human U2-OS cell line and mouse cell line NIH 3T3. Representative multi-color images showing the protein of interest in green are displayed. The images also include markers for the nucleus (blue), microtubules (red) and ER (yellow). As stated in database, all proteins are stained in U-2 OS for localizing the whole human proteome on a subcellular level in one specific cell line. In addition to the human cell lines, many proteins have been stained in the mouse cell line NIH 3T3, given that the human and mouse genes are orthologous.

MTHFD2 Prognosis Analysis

We then evaluated the influence of MTHFD2 expression on the overall survival of LGG patients by Gepia and TISIDB databases. For deeper understanding the influence of MTHFD2 expression on the patient's survival, we used the clinical data of LGG patients from TCGA Lower Grade Glioma (LGG) cohort for conducting survival analysis. The LGG patients were divided into high- and low-expression groups according to the median of MTHFD2 expression. Subsequently, the influence of MTHFD2 expression on overall survival was analyzed based on age, gender, tumor subtypes, IDH mutation status, pharmaceutical therapy, and radiation therapy using Kaplan-Meier analysis and Log rank test. Moreover, Cox regression analysis was performed to predict the independent prognostic role of MTHFD2 for overall survival in LGG.

Functional Enrichment Analysis

In order to explore the potential function of MTHFD2, we firstly detected its co-expressed genes in LGG through

cBioportal database. The genes with absolute correlation >0.5 , $P < 0.001$ and $q < 0.001$ were selected for further functional analysis. We used BiNGO plug-in of Cytoscape to explore the enriched biological processes of these identified genes, and ClueGO plug-in to predict the associated KEGG pathways. Further, we performed the GSEA analysis to explore the potential mechanism of MTHFD2 in LGG. The analysis criteria for GSEA were set as follows: number of permutations (1000), permutations type (gene_set), enrichment statistic (weighted), metric for ranking genes (person), genes list ordering mode (descending). The terms with $FDR < 25\%$ and $P < 0.05$ were considered as significant pathways.

Interactions Analysis on MTHFD2 with Tumor-Immune System

We used the TISIDB to explore the association of MTHFD2 expression with immune subtypes and molecular subtypes in LGG. The immune subtypes include C1 (wound healing), C2 (IFN-gamma dominant), C3 (inflammatory), C4 (lymphocyte depleted), C5 (immunologically quiet) and C6 (TGF- β dominant). Molecular subtypes contain Classic-like, Codel, G-CIMP-high, G-CIMP-low, Mesenchymal-like and PA-like.

Statistical Analysis

All the statistical analyses were performed using SPSS 19.0. Independent *t*-test or Mann-Whitney *U*-test were performed for comparisons between the two groups. ANOVA or Kruskal-Wallis test was performed for multiple comparisons followed by Bonferroni's post-hoc test. Survival analysis was performed by Kaplan-Meier method and Log rank test. *P* value less than 0.05 was regarded as statistical significance.

Results

Expression Analysis in LGG

The MTHFD2 expression profile in human cancers (Figure 1A) presented that MTHFD2 was highly expressed in most cancer types including LGG, while down-regulation was observed in LAML (Acute Myeloid Leukemia) and THCA (Thyroid carcinoma) (all $P < 0.05$). Differential expression analysis (Figure 1B) further confirmed high expression of MTHFD2 in LGG compared with normal group ($P < 0.05$). Further, comparison analysis using GSE60898 dataset showed that age of LGG patient was associated with MTHFD2 expression, and higher

MTHFD2 expression was observed in adult patient (Figure 1C, all $P < 0.001$). However, no correlation was observed between MTHFD2 expression and BRAF genetic status, locations, primary or recurrent tumor, and primary tumor that further progressed (Figure 1D–G, all $P > 0.05$).

Apart from above parameters, we also analyzed the correlation of MTHFD2 expression with other characteristics of patients using TCGA Lower Grade Glioma (LGG) cohort data. These samples just contained G2 and G3 patients, and this study has removed all G3 patients in the further investigations. The clinical characteristics of LGG patients in TCGA Lower Grade Glioma (LGG) cohort is presented in Table 1. Correlation in Figure 2A indicated that IDH mutation status of patient was related to MTHFD2 expression, and higher expression was observed in patients with IDH mutation ($P = 0.0260$). Expression difference was not observed under different age, gender, tumor subtypes, pharmaceutical therapy, and radiation therapy (Figure 2B–F).

We then evaluated the MTHFD2 mRNA expression in the human brain. The results indicated that MTHFD2 was detected in all with a low region specificity (Figure 3A). Immunohistochemistry images (Figure 3B) showed that MTHFD2 protein was not detected in normal endothelial cells, but showed a weak intensity in normal glial cell. The MTHFD2 protein staining was not detected in cancer cell, but a weak intensity was observed. Subcellular location showed that MTHFD2 was mainly localized to the mitochondria both in human and mouse cancer cells (Figure 3C).

Prognosis Analysis in LGG

The effect of MTHFD2 expression on the clinical outcome of LGG patients was subsequently predicted (Figure 4). Survival analysis in Gepia suggested that MTHFD2 expression statistically correlated with the overall survival of patients, and MTHFD2 high expression prolonged the survival time of patients compared with low expression ($P < 0.001$). The results from TISIDB also demonstrated the favorable impacts of MTHFD2 high expression on the overall survival of patients ($P < 0.001$).

We then performed restrict survival analysis using TCGA Lower Grade Glioma (LGG) cohort data. The results indicated that expression of MTHFD2 was statistically related with overall survival time of patients with age ≥ 45 years (Table 2), and higher risk was observed in MTHFD2 low expression group ($HR = 4.530$, $P = 0.040$). However, survival difference between MTHFD2 high and low expression groups was not observed under other parameters (all $P > 0.05$).

Table 1 The Clinical Characteristics of LGG Patients in TCGA Lower Grade Glioma (LGG) Cohort

Characteristics		Sample Size	Mean±SE	P
Age	<45	177	4.298±0.085	0.321
	≥45	80	4.149±0.118	
Subtypes	Astrocytoma	65	4.117±0.139	0.478

	Yes	45	4.455±0.134	

found, and 175 genes with absolute value of correlation coefficient > 0.5 and P<0.001 were selected for further enrichment analysis.

We then explored the potential biological process associated with the 175 co-expressed genes by BiNGO of Cytoscape. The results (Figure 5) indicated that

these co-expressed genes significantly participated in cellular process, cellular component organization, cell cycle, cell division, nuclear division, DNA replication and DNA metabolic process (all $P<0.001$).

The potential KEGG pathways associated with 175 genes were explored through ClueGO of Cytoscape. Pathway analysis in **Figure 6A** showed that most of these genes participated in Oocyte meiosis (20.0%) and

Table 2 Restrict Survival Analysis on LGG Patients in TCGA Lower Grade Glioma (LGG) Cohort

Fanconi anemia pathway (20.0%). Another important pathway detected included Cellular senescence (10.0%), p53 signaling pathway (10.0%), Cell cycle (10.0%), DNA replication (10.0%), One carbon pool by folate (10.0%) and Pyrimidine metabolism (10.0%). Among these pathways, MTHFD2 statistically referred to the pathway of One carbon pool by folate (Figure 6B).

We further explored the potential mechanism associated with MTHFD2 in LGG through GSEA analysis. The GSEA analysis totally detected 10 positive and 19 negative MTHFD2-associated pathways involved in LGG. According to GSEA analysis, we found that MTHFD2 high expression was statistically and positively related to One carbon pool by folate pathway (Figure 7A, $P=0.0181$). The detailed information about One carbon pool by folate pathway is presented in Figure 7B.

Tumor-Immune System Interaction Analysis on MTHFD2

We finally explored the interaction of MTHFD2 with tumor-immune system in TISIDB. The results indicated that MTHFD2 was statistically associated with immune subtypes in LGG (Figure 8A, $P<0.001$), and higher expression was observed in C5 (immunologically quiet) subtype. In addition, molecular subtypes in LGG also affected the MTHFD2 expression (Figure 8B, $P<0.001$), and Codel subtype showed a higher expression.

Discussion

Previous study has showed that MTHFD2 expression is low or absent in a large panel of normal tissues, and expressed in the developing embryo but absent in most healthy adult tissues, even those that are proliferating.¹⁹ MTHFD2 has been proved to be highly expressed in human cancers and associated with the tumor progression. Previous research indicated that MTHFD2 may serve as a tumor promoter by promoting cell proliferation. For example, MTHFD2 was found highly expressed in colorectal cancer (CRC) cells, and silence of MTHFD2 expression inhibited the proliferation, weakened the migration ability and promoted the apoptosis of CRC cells.²⁰ MTHFD2 was also significantly overexpressed in non-small cell lung cancer (NSCLC) tissues, and knockdown of MTHFD2 resulted in reduction of tumor cell growth and tumorigenicity.²¹ In addition,

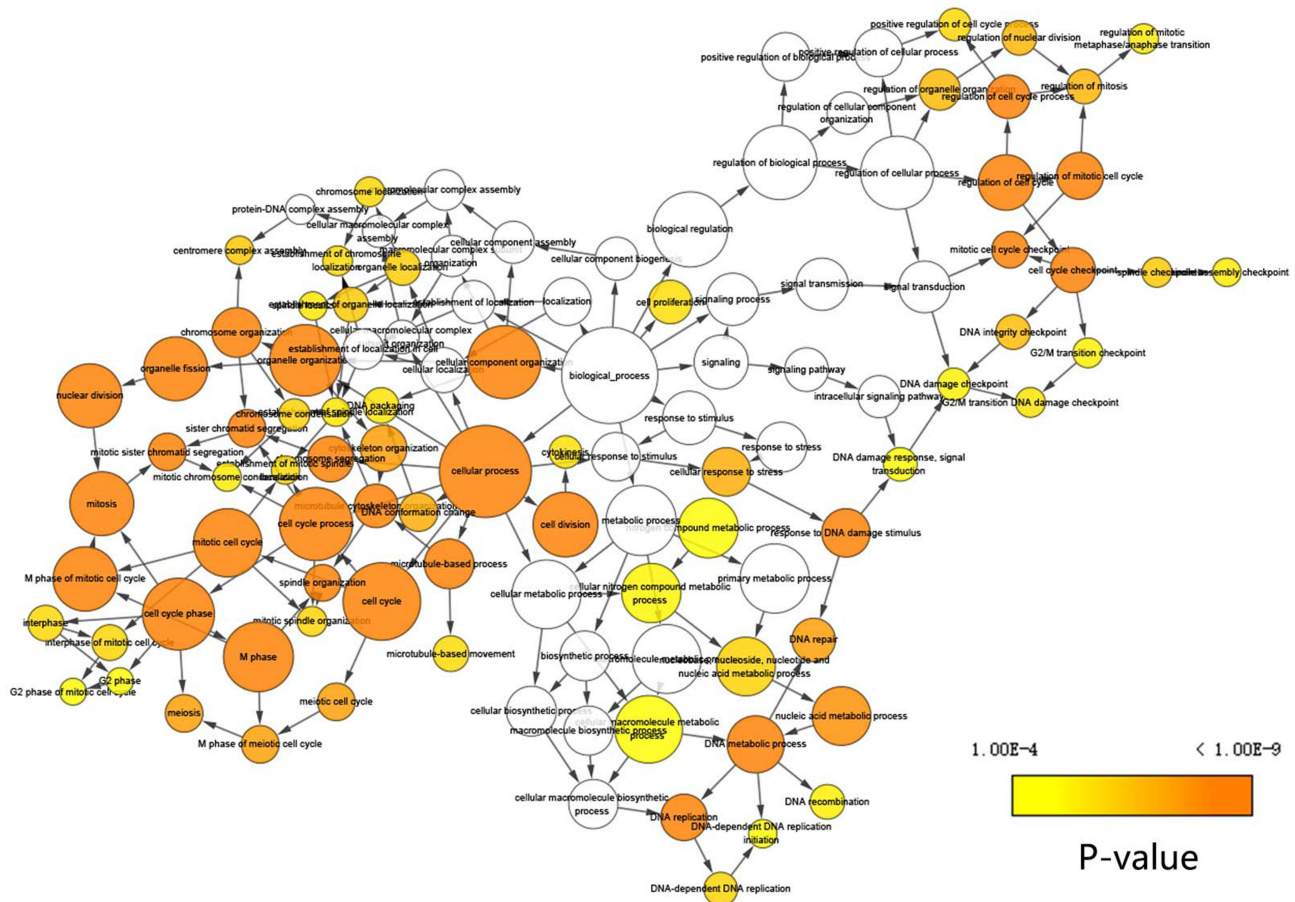

Figure 5 The enriched biological process of 175 co-expressed genes with MTHFD2.

MTHFD2 over-expression was associated with cell proliferation and vimentin-modulated migration and invasion in renal cell carcinoma (RCC).²² Moreover, MTHFD2 expression was significantly associated with the clinical outcome of patients, and high expression of MTHFD2 resulted in poor prognosis in hepatocellular carcinoma,²³ esophageal squamous cell carcinoma²⁴ and breast cancer.²⁵ Taken together, MTHFD2 was oncogenic in nature and may serve as a prognostic indicator.

In this study, we found that MTHFD2 mRNA was over-regulated in LGG patients compared with normal group. Among LGG patients, higher expression was observed in adult patients. However, survival analysis indicated that MTHFD2 high expression was conducive to prognosis of LGG patients, especially facilitated the clinical outcome of patients with age ≥ 45 years. It seemed that MTHFD2 high expression exerted a positive role in LGG. The impact of MTHFD2 on LGG was different from that in other cancer types. We speculated that function of MTHFD2 exerted cancer type specificity.

It should be noted that previous findings about MTHFD2 in brain glioma seemed to be controversial. A bioinformatics analysis¹⁷ by Liu et al found that MTHFD2 was identified as a down-regulated gene in glioma, and the down-regulation of MTHFD2 was closely associated with a decreased overall survival among patients with glioma. However, Xu et al analyzed the expression of MTHFD2 in glioma tissues through TCGA analysis and qRT-PCR, finding that expression of MTHFD2 was significantly greater in glioma tissues than in normal tissues, and MTHFD2 was a protected factor for glioma patients as high expression with a long survival time.²⁶ Gao et al demonstrated that MTHFD2 significantly correlated with overall survival, and it was a protected factor of glioblastoma multiforme patients.²⁷ Our analysis also indicated the up-regulation of MTHFD2 in LGG, and MTHFD2 high expression was favorable to the overall survival of LGG patients. According to our investigation, the subjects in Liu et al and Xu et al studies were all patients with high-grade glioma, but the result of

Figure 6 Potential enriched KEGG pathways of 175 co-expressed genes with MTHFD2. **(A)** The top 8 significant pathways. **P<0.01. **(B)** Interaction between pathway and related genes.

Figure 7 The GSEA analysis on MTHFD2 in LGG. **(A)** One carbon pool by folate pathway positively associated with MTHFD2. **(B)** Pathway plot of one carbon pool by folate pathway. The numbers mean the enzyme code (EC). For example, EC: 1.5.1.3 represents dihydrofolate reductase.

MTHFD2 expression analysis were opposite. Current study contained patient with low-grade glioma in G2, expression analysis indicated its up-regulation which agreed with Xu et al study. Although differences were observed about MTHFD2 expression among existing research in brain glioma, the assessment on prognostic value of MTHFD2 seemed to be consistent. All study

suggested that MTHFD2 high expression was conducive to the prognosis of patients with glioma compared with low expression. The causes and mechanisms behind the discrepant expression profiles remained elusive and deserved further investigations. We also performed pathway enrichment analysis to explore the potential MTHFD2-associated mechanism

Figure 8 Tumor-immune system interaction analysis on MTHFD2. (A) Associations between MTHFD2 expression and immune subtypes in LGG. (B) Associations between MTHFD2 expression and molecular subtypes in LGG.

involved in LGG. Both KEGG and GSEA analysis indicated that MTHFD2 mainly participated in pathway of one carbon pool by folate. Metabolic pathway was the common mechanism related to MTHFD2. Folate-mediated one-carbon metabolism plays a central role in a broad array of metabolic processes required for the survival and growth of tumor cells.²⁸ The patients with aminopterin treatment, an intermediate of folate metabolism, showed clinical, hematologic and pathological evidence of improvement.²⁹ Metabolism reprogramming was one of the most active fields in cancer research, and the effects and consequences of elevated MTHFD2 in brain low-grade glioma were largely unknown. Thus, experiment and clinical studies were needed to understand its potential functional role in brain glioma.

In addition, recent studies have highlighted the critical value of MTHFD2 as a therapeutic target for treatment of cancers. Xu et al suggested that microRNA-940 could inhibit glioma progression by blocking mitochondrial folate metabolism through targeting of MTHFD2.²⁶ Yam et al indicated that microRNA-33a-5p suppressed the growth and migration of colorectal cancer cell by inhibiting MTHFD2.³⁰ Li et al reported that upregulation of miR-504-3p was associated with favorable prognosis of acute myeloid leukemia and may serve as a tumor suppressor by targeting MTHFD2.³¹ Moreover, folate analog as MTHFD2 inhibitor displayed therapeutic activity against colorectal cancer.³² These studies implied the significance of MTHFD2 as an effective target for more cancer treatment in the future.

Conclusions

This current study demonstrated that mRNA expression of MTHFD2 was significantly increased in LGG, and associated with age, and TP53-mutation status of patients. High expression of MTHFD2 favorably prolonged the patient's survival time, and MTHFD2 was determined as

an independent prognostic biomarker for overall survival of LGG patients. We further demonstrated that MTHFD2 was positively implicated in the pathway of one carbon pool by folate. Our research initially emphasized the importance of MTHFD2 in LGG, and the experimental intervention must be icing on the cake for this research.

The International Journal of General Medicine is an international, peer-reviewed open-access journal that focuses on general and internal medicine, pathogenesis, epidemiology, diagnosis, monitoring and treatment protocols. The journal is characterized by the rapid reporting of reviews, original research and clinical studies

across all disease areas. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
