Abstract: This study aimed to analyze the diagnosis and treatment process of patients with hematogenous disseminated pulmonary tuberculosis after treatment with in vitro fertilization-embryo transfer (IVF-ET). We retrospectively analyzed the clinical data, including imaging and etiological data, the use of antimicrobials, metagenomic next-generation sequencing (mNGS) results, and the treatment process, of a patient who underwent IVF-ET due to an obstruction in the fallopian tube; after the treatment, she developed a persistent fever with shortness of breath and suffered a spontaneous abortion. Due to the failure of other treatment modalities, fiber optic bronchoscopy was performed, and the alveolar lavage fluid was obtained for mNGS. Tests for *Mycobacterium tuberculosis* and rifampicin resistance (Xpert MTB/RIF) showed positive and negative results, respectively. Subsequently, anti-tuberculosis treatment with isoniazid, rifampicin, pyrazinamide, and ethambutol was administered. After the patient's condition improved, she was transferred to a specialized tuberculosis hospital for further treatment, where she died one month later from multiple organ failure. From this case, we conclude that clinicians should remain highly vigilant for pulmonary infection with *M. tuberculosis* in pregnant women, particularly in patients treated with IVF-ET, and check for its presence as soon as possible.

Keywords: tuberculosis, IVF-ET, maternal, mNGS

Introduction

Tuberculosis (TB) is a global infectious disease that seriously endangers human health and is one of the top ten causes of death worldwide.¹ According to the World Health Organization (WHO), approximately 10 million new TB cases occurred worldwide in 2019. The levels of estrogen and progesterone increase in pregnant women. This inhibits T lymphocytes and leads to an increased incidence of TB infection. In patients with in vitro fertilization-embryo transfer (IVF-ET), the peak serum estrogen levels are several times higher than those in normal individuals. This is conducive to the reproduction of *Mycobacterium tuberculosis* and may be one of the factors that aggravate disease progression.^{2,3}

The exact scale of TB during pregnancy remains uncertain globally, and a large number of active TB cases in pregnant women are likely to remain undetected.⁴ As patients with TB do not show obvious symptoms during pregnancy, and radiographic imaging examination is limited due to the patient's condition, the proportion of patients that have TB during pregnancy and are not diagnosed and treated timely may be as high as 40%.⁵⁻⁷ These patients are not diagnosed until the disease

Graphical Abstract

has advanced to a severe stage. Pregnancy and childbirth are the two primary causes of severe TB in women; it has been reported early in 2015 that the pregnant women who died from TB were all in the advanced stage of the disease.^{8,9}

Therefore, the early diagnosis of TB is particularly important in pregnant women, especially those receiving IVF-ET treatment. However, currently, there are some challenges in the clinical diagnosis of TB after IVF-ET,⁹ because of a lack of relevant literature. Here, we report a case of blood-type disseminated pulmonary TB after IVF-ET and analyze the diagnosis and treatment process to provide a reference for improving the early diagnosis and treatment success rate of pulmonary TB in pregnant women.

Case Report

The patient was a 28-year-old Asian female farmer. Due to fever and shortness of breath after spontaneous abortion (one week earlier), which aggravated over the next two days, she was admitted to the Department of Critical Care

Medicine, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi, China on October 17, 2019.

The patient had received IVF-ET treatment due to an obstruction in the fallopian tube, and the pregnancy was successfully established on July 12, 2019. However, vaginal bleeding began on October 8, 2019. On October 10, 2019, she had a spontaneous abortion on the way to the hospital and underwent uterine clearance at the Northwest Women's and Children's Hospital, Xi'an, Shaanxi, China. During treatment, the patient started feeling cold and developed shortness of breath, fever, and chills. Her body temperature was 38.7 °C, and she had an occasional, mainly dry cough, accompanied by dizziness and general fatigue. She went to the Shaanxi Women's and Children's Hospital, where a five-day oral treatment with cefpodoxime proxetil was initiated; however, there was no improvement in her condition. Two days before admission to the intensive care unit (October 15), she complained of worsening shortness of breath. Her body temperature at the time was 38 °C, and she had an occasional cough. She was admitted to the local hospital one day before admission

Figure 1 (A) few nodular shadows in the upper lobes of both lungs, (B) ground-glass dense opacities in both lungs, (C) multiple nodules in the upper lobes of both lungs, (D) multiple patchy high-density shadows in both lungs with uneven density.

into the intensive care unit (October 16); chest computed tomography (CT) revealed scattered ground-glass dense opacities in both the lungs. Furthermore, we noticed a few nodular shadows in the upper lobes of both the lungs of the patient (Figure 1A and B). With a diagnosis of severe pneumonia, she was referred to the emergency department of the First Affiliated Hospital of Xi'an Jiaotong University. Her body temperature peaked at 40 °C, which was accompanied by shivering. Oxygen was supplied using a mask at 5–8 L/min, and oxygen saturation fluctuated between 90–93%. Infection-related indices, such as white blood cell count (WBC), neutrophilic granulocyte percentage (NEUT), and procalcitonin (PCT), increased; thus, cefoperazone sodium/sulbactam sodium and moxifloxacin were administered as an anti-infection therapy. However, the patient's shortness of breath worsened, and her respiratory rate increased. The pulse oxygen saturation decreased to 89%, and the patient was connected to a non-invasive ventilator to assist breathing. Six hours later, the patient still had dyspnea and became irritable. The oxygen saturation fell to 44%. Arterial blood gas analysis revealed type I respiratory failure.

Physical examination of the patient revealed the following: a body temperature of 36.9 °C, a heart rate of 123 beats/min, a respiratory rate of 26 breaths/min, and

blood pressure of 86/54 mmHg. She was conscious, but had an emaciated body. Ventilation was assisted via a ventilator and tracheal tube intubation. The breathing sound of both lungs was rough, and few wet rales were heard. There was no abnormality in heart and abdominal examination, and slight pitting edema in the lower limbs was observed.

The laboratory test results after admission are listed in Table 1. The imaging results are listed in Table 2.

On October 17, 2019, she was admitted to the Department of Critical Care Medicine and was initially diagnosed with severe pneumonia, acute respiratory distress syndrome (ARDS), septic shock, and moderate anemia. The patient was administered anti-infective moxifloxacin therapy. Due to septic shock, the patient was given fluid rehydration (initial fluid volume: 30 mL/kg) and administered noradrenaline to raise her blood pressure. Thymopetidum injection was used to enhance immunity, and vitamin C was used as an anti-inflammatory agent. A bedside chest X-ray scan revealed double-lung pneumonia (Figure 2A). Fiberoptic bronchoscopy was performed on the same day, and small amounts yellow sputum, scabbing, and mucosa were observed. The alveolar lavage fluid was collected for etiological examination. On the second day of admission, her body temperature peaked to 38 °C; her blood pressure was 109/84 mmHg under

Table 1 Summary of Laboratory Test Indicators in the Patient

Variable	Value	Reference/ Normal Range	Elevated/ Normal/Low
Blood cell count			
Haemoglobin	75	110–150 g/L	Low
White cell count	9.66×10^9	$3.5\text{--}9.5 \times 10^9/\text{L}$	Elevated
Neutrophil	97.0%	40–75%	Elevated
Platelets	141×10^9	$125\text{--}350 \times 10^9/\text{L}$	Normal
Lymphocyte count	0.16×10^9	$1.1\text{--}3.2 \times 10^9/\text{L}$	Low
Eosinophils	0.01×10^9	$0.02\text{--}0.52 \times 10^9/\text{L}$	Low
Infection and inflammatory markers			
C-reactive protein	96.7	0–10 mg/L	Elevated
Erythrocyte sedimentation rate	23	0–20 mm/h	Elevated
Procalcitonin	8.89	<0.5 ng/mL	Elevated
Interleukin-6	174.3	0–7 pg/mL	Elevated
Respiratory Virus antibodies	Legionella pneumophila weakly positive	Negative	Elevated
Epstein-Barr Virus DNA	Nuclear antigen IgG 327 U/mL; Capsid antigen IgG 34.5 U/mL	<20 U/mL	Elevated
Cytomegalovirus DNA	IgG positive	Negative	Elevated
Sputum smear (bacterial/fungus)	Normal	-	Normal
Bronchoalveolar lavage fluid culture, blood culture, urine culture	Normal	-	Normal
<i>Legionella pneumophila</i> antigen in urine	Normal	-	Normal
Bronchoalveolar lavage fluid galactomannan	0.22	<0.5 µg/L	Normal
1,3-beta-D-glucan	<10 pg/mL	<60 pg/mL	Normal
Tuberculosis			
Tuberculosis-infected T cell	Antigen A 5 SFCs/ 2.5×10^5 PBMC; Antigen B 0 SFCs/ 2.5×10^5 PBMC	<6 SFCs/ 2.5×10^5 PBMC	Normal
Acid-fast stain in sputum smear	Normal	-	Normal
Tuberculin test	Normal	-	Normal
Rheumatology			
Autoantibody profile	Normal	-	Normal
Immune	Normal	-	Normal
Rheumatism			
C-reaction protein	87.6 mg/L	0–10 mg/L	Elevated
CD8 ⁺ T-cells	30.29%	18.1–29.6%	Elevated
CD4 ⁺ /CD8 ⁺ T-cells	1.57	0.8–2.1	Normal
Thyroid function	Normal	-	Normal
Liver and kidney function	Normal	-	Normal
Albumin	19.1	40–55 g/L	Low
Coagulation profile	Normal	-	Normal
Arterial blood gas (mechanical ventilation; PEEP, 12 cmH₂O; FiO₂, 100%)			
PH	7.335	7.35–7.45	Low
PCO ₂	32	35–45	Low
PaO ₂	83	83–108	Normal
HCO ₃ ⁻	17.9	21–27 mmol/L	Low
BE	-8.0	-3 to +3	Low
Lactate	3.6	0.5–1.6 mmol/L	Elevated

Table 1 (Continued).

Variable	Value	Reference/ Normal Range	Elevated/ Normal/Low
Urinalysis			
Protein	2+	-	Elevated
Occult blood	3+	-	Elevated
White blood cell	-	-	Normal
Myocardial enzyme			
LDH	1073 U/L	120–250 U/L	Elevated
HBDH	767 U/L	72–182 U/L	Elevated
CK, CKMB	Normal	-	Normal
NT-proBNP	162.3 pg/mL	0–125 pg/mL	Elevated
Faeces test	Normal	-	Normal

Abbreviations: PEEP, positive end expiratory pressure; FiO₂, fraction of inspiration O₂; PH, pondus hydrogenii; PCO₂, partial pressure of carbon dioxide; PaO₂, arterial partial pressure of oxygen; HCO₃⁻, bicarbonate; BE, base excess; LDH, lactate dehydrogenase; HBDH, hydroxybutyrate dehydrogenase; CK, creatine kinase; CKMB, creatine kinase myocardial band; NT-proBNP, N-terminal pro-brain natriuretic peptide.

Table 2 Summary of Ultrasound and Fiberoptic Bronchoscopy Results in the Patient

Variable	Check Date	Value
Echocardiography	18 Oct.	EF59%, pulmonary artery pressure is 35mmHg, no abnormalities in heart structure and blood flow
Abdominal ultrasound	17 Oct.	No abnormalities
Pelvic ultrasound	17 Oct.	A small amount of fluid (27mm)
Gynecological ultrasound	17 Oct.	Endometrial cavity fluid 23mm×7mm(a little), uterus size 87×69×59(mm), intima media thickness 14mm, uneven echo; Double attachment is normal
Fiberoptic bronchoscopy	17 Oct.	Bronchial patency, the mucosa is slightly congested, the surface was covered with a small amount of yellow sputum scab

noradrenaline treatment (0.2 µg/kg/min), the concentration of oxygen inhaled using mechanical ventilation was 80%, and she was still short of breath and sweating. The patient was given sedation and analgesic treatments. The PCT increased from 8.89 to 18.24 ng/mL, and the C-reactive protein (CRP) level was as high as 142.4 mg/L. The causative pathogen remained unknown, and anti-infection treatment was administered. However, the levels of relevant infection-related markers continued to rise. Therefore, anti-infection treatment with meropenem and linezolid was started on October 19. The treatment led to a gradual improvement in infection indices. On October 21, the PCT was 2.24 ng/mL, blood leukocyte count was 4.49×10⁹/L, the proportion of neutrophils was 82.2%, blood pressure (BP) was 110/70 mmHg after stopping noradrenaline treatment, heart rate (HR) was 86 bpm,

respiration rate (RR) was 18 breaths per minute, and the saturation of pulse oxygen (SpO₂) was 98%. The use of the ventilator was reduced, positive end-expiratory pressure (PEEP) was 8 cm H₂O, and the fraction of inspiration O₂ (FiO₂) was 45%. Arterial blood gas analysis revealed a pH of 7.438, PCO₂ of 40.1 mmHg, PO₂ of 118 mmHg, HCO₃⁻ of 26.8 mmol/L, BE (base excess) of 2.7 mmol/L, and lactate levels of 2.0 mmol/L. The patient was discharged from the bed with a ventilator, for exercise. Although the infection-related indicators of the patient improved and her general condition was stable, the patient still had a fever with a peak body temperature of 38.4 °C. This occurred mainly in the afternoon and evening and was accompanied by sweating. Further, the CRP was still as high at 90.5 mg/L. Abdominal, pelvic, and gynecological ultrasonography revealed no obvious abnormalities.

Figure 2 (A) A bedside chest X-ray revealed double-lung pneumonia, (B) extensive exudation in both lungs, with small nodules visible, especially in the lower lobes of both lungs.

The examination indices of bacteria, fungi, TB, viruses, specific pathogenic bacteria, and factors related to non-infectious fever were all normal (Table 1), and no pathogenic bacteria were found. However, the patient failed to leave ventilator support. Re-examination of chest CT revealed multiple nodules in the upper lobes of both the lungs and multiple patchy high-density shadows with uneven density in both the lungs (Figure 1C and D). The chest CT showed no improvement on October 16. Combined together, the patient's pathogenesis, relevant examination, and treatment process led us to believe that she had no infectious diseases. Therefore, we sent the alveolar lavage fluid for an mNGS test. The mNGS results showed that only three sequences of the *M. tuberculosis* complex group were present; moreover, the Xpert results were positive for *M. tuberculosis* but negative for rifampicin resistance. Combined with the symptoms and signs of the patient, a diagnosis of pulmonary TB was established, and hematogenous disseminated pulmonary TB was considered. Accordingly, the administration of moxifloxacin, meropenem, and linezolid was stopped. Isoniazid, rifampicin, pyrazinamide, and ethambutol were administered as anti-TB therapy. Re-examination of chest radiographs on October 25 revealed extensive exudation in both the lungs, with small nodules visible, particularly in the lower lobes of both the lungs (Figure 2B). On October 28, the patient was referred to a specialized TB hospital for treatment. *M. tuberculosis* culture results were positive. Quadruple anti-TB therapy and ventilator assistance were continued. One month after being transferred from our hospital, the patient died of multiple organ failure.

Discussion

TB is a major cause of death in women of child-bearing age and a common non-obstetric cause of maternal death.¹⁰ Studies have shown that women are at a significantly increased risk of active TB infection during pregnancy and postpartum.^{11,12} An estimated 216,500 (95% confidence interval, 192,000–247,000) pregnant women were diagnosed with active TB globally in 2011,¹⁰ and there may be a large number of cases of undetected active TB during pregnancy.⁴ Ye et al⁹ reported six cases of pregnant women with TB, in 2019, in whom the hormone level changes during pregnancy led to decreased T cell activity and immunosuppression. This resulted in the reactivation and spread of *M. tuberculosis*, ultimately leading to hemorrhagic disseminated and extrapulmonary TB.

Reproductive system TB is an important factor that causes tubal infertility, and it has been reported that 20% of the cases of female primary infertility are caused by reproductive system TB.^{13,14} TB of the female reproductive system leads to chronic inflammatory lesions of the reproductive organs. The incidence of fallopian tube TB is highest, followed by the TB of the endometrium and ovary.¹⁵ The patient's condition is insidious, and there are no other clinical manifestations except infertility. The incubation period from initial infection to the expression of urogenital TB is usually 5–40 years.¹⁵

With the gradual maturity of IVF-ET, an increasing number of infertile patients have received this treatment and a large proportion of them are patients with occult genital TB whose TB is activated after receiving IVF-ET.¹⁶ After pregnancy, vascular permeability increases, and a large number of TB bacilli spread throughout the body through the bloodstream. This results in hematogenous disseminated and extrapulmonary TB,¹⁷ which often presents as severe pneumonia with rapid progression and poor prognosis. Gai et al¹⁸ recently reported seven cases of acute miliary tuberculosis in pregnancy after in vitro fertilization and embryo transfer, suggesting that patients with miliary TB have poor pregnancy outcomes. The coexistence of primary infertility, untreated prior pulmonary TB, and fallopian tube obstruction is a high-risk factor for TB dissemination. Therefore, clinicians should be aware of the signs of TB before administering a course of IVF-ET treatment. In patients undergoing IVF, estrogen levels suddenly increase during ovulation induction and the peak levels of serum estrogen are several times higher than the peak value of serum estrogen levels in the natural

cycle. This is conducive to the reproduction of *M. tuberculosis*.³ At the same time, the estrogen, progesterone, and chorionic sex hormones can directly inhibit T cells and induce lymphocyte apoptosis, thereby inhibiting the cellular immune function of the body after superovulation and embryo transfer. This also leads to the rapid reproduction of *M. tuberculosis*,^{19–21} which may aggravate the progression of the disease. In addition, the inhibition of lymphocyte function due to glucocorticoid use during IVF-ET therapy may lead to increased risks of TB infection and reactivation.

Studies have shown⁹ that patients with TB after IVF-ET usually exhibit a fever, with body temperatures as high as 40 °C and pulmonary imaging changes. Most spontaneous abortions occur at 12 to 16 weeks after embryo transfer, which is mainly caused by severe TB toxemia and chorioamnionitis due to the spread of *M. tuberculosis* through the blood to infect the placenta, thus leading to abortion and fetal death. However, in these patients, early TB-related examinations, such as purified protein derivative (PPD) test, sputum TB smear, TB polymerase chain reaction (PCR), and T-spot, are mostly negative. Therefore, the diagnosis is somewhat difficult, and it is usually 12–13 days from onset to a definite diagnosis.⁹ In this case, spontaneous abortion occurred 12 weeks after IVF-ET; high fever (body temperature of 40 °C) and pulmonary imaging changes occurred after abortion. The conventional TB tests were negative. Three sequences of TB bacteria were detected in alveolar lavage fluid mNGS, and the Xpert MTB/RIF test was positive, confirming the final diagnosis. The time from onset to diagnosis was approximately six days. Quadruple anti-TB therapy was administered after the diagnosis. After referral to a specialized TB hospital for treatment, sputum TB bacterial culture was used to identify the responsible *Mycobacterium*. However, the damage caused by the tuberculous toxin to the whole body causes MODS, eventually resulting in the death of the patient. The period from the onset to death is 50 days. With the help of mNGS detection technology, the pathogen could be rapidly and accurately identified, allowing a diagnosis six days earlier than the average time reported in the literature. Untreated prenatal TB increases the risk of perinatal complications. This includes preeclampsia, intrauterine growth delay, prenatal bleeding, low birth weight, low Apgar score at birth, and early fetal death.^{22,23} Early treatment can reverse this negative effect on perinatal outcomes. Late diagnosis and incomplete or partial pharmacotherapy are associated with poor

outcomes.²⁴ Therefore, early diagnosis and treatment of TB are of great significance for improving the survival rate of pregnant women and new-borns.²⁵

As a powerful detection method, mNGS assists in the diagnosis of patients with acute and severe diseases.²⁶ Studies have shown that in terms of pathogen identification, the consistency between mNGS and traditional microbial culture detection results is as high as 77.78%.²⁷ Additionally, it has been reported that mNGS is superior to traditional cultures in the identification of rare infectious pathogens, especially *M. tuberculosis* (odds ratio=4; 95% CI, 1.7–10.8; $P < 0.01$), and the sensitivity of mNGS is better than that of cultures (52.5% vs 34.2%) with previous antibiotic use, with little effect on the results.²⁸ Xie et al²⁹ found that mNGS can determine the pathogen in patients with severe pneumonia in early stages, guide the application of antimicrobial drugs, and improve the mortality rate of patients with severe pneumonia. Therefore, it should be widely used in the diagnosis of unidentified infections to assist in pathogen screening, as it has great potential as a diagnostic tool.³⁰

Conclusions

In conclusion, when severe infection occurs in patients undergoing IVF-ET, high vigilance is necessary, and an *M. tuberculosis* infection test should be conducted as soon as possible. Application of alveolar lavage fluid mNGS is helpful in improving the early etiological diagnosis of patients and is effective in the clinical setting; additionally, it helps in improving the treatment success rate of patients with severe pulmonary infections.

Infection and Drug Resistance

Dovepress

Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of

antibiotic resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
