Medicine, Department of Internal
Medicine, Division of Immunology/
Allergy Section, Cincinnati, OH, USA

Abstract: Recently, multiple C1 inhibitor (C1-INH) replacement products have been approved for the treatment of hereditary angioedema (HAE). This review summarizes HAE and its current treatment modalities and focuses on findings from bench to bedside trials of a new C1-INH replacement, conestat alfa. Conestat alfa is unique among the other C1-INH replacement products because it is produced from transgenic rabbits rather than derived from human plasma donors, which can potentially allow an unlimited source of drug without any concern of infectious transmission. The clinical trial data generated to date indicate that conestat alfa is safe and effective for the treatment of acute HAE attacks.

Keywords: androgens, adverse events, patients, HAE attacks

Hereditary angioedema Clinical presentation

Hereditary angioedema (HAE) is a rare disorder characterized by recurrent attacks of swelling that may involve the peripheral extremities (most common), intestines, trunk, genitalia, face, and upper respiratory tract. The frequency of attacks varies greatly, but can occur as often as several times a week. Time of onset, incidence, location, and severity of clinical manifestations also vary between individuals even within the same family.¹ Mechanical trauma, infections, menstruation, pregnancy, oral contraceptives, and angiotensin-converting enzyme (ACE) inhibitors are examples of potential attack triggers.²⁻⁴ Edema is not accompanied by erythema, pruritus, or urticaria and it usually resolves over a couple of days.⁵ Abdominal complaints are the second most frequent manifestation. Abdominal symptoms include nausea, vomiting, colicky pain, and diarrhea.⁵⁻⁷ These symptoms have been misinterpreted as an acute abdomen leading to unnecessary surgery. Edema of the upper airway is the most dangerous manifestation of HAE. Asphyxiation resulting in airway obstruction is the leading cause of death.⁸ Rarely, cerebral edema can develop with neurological symptoms. Pulmonary edema has not been reported as a common complication, presumably because bradykinin is effectively metabolized in the lung.⁹

Epidemiology

The prevalence of HAE has been estimated to range from 1:10,000 to 1:50,000 persons in the United States (US).¹⁰ Fifty percent of initial attacks begin in the first decade of life (average age 11 years) and an additional 30% during the second decade of life. In undiagnosed HAE, the mortality rate can be as high as 30% to 50%.^{11,12}

Mechanism

Most HAE patients have either a quantitative (type I) or a functional (type II) defect in the C1 inhibitor (C1-INH), which is an important regulator of the complement, fibrinolytic, kallikrein-kinin, and coagulation pathways.^{13,14} For most HAE patients, inheritance is autosomal dominant, although 25% of cases can occur as the result of de novo mutations.¹⁵ However, in 5% of apparent HAE cases, no mutation of the C1-INH gene can be demonstrated.¹³ A third type of HAE, referred to as type III, characterized by normal quantitative and functional C1-INH levels and estrogen dependence, occurs more frequently in females. The original cases reported were associated with a missense mutation in Hagemann factor (Factor XII) although this observation has not been consistently observed in other cases of type III HAE.¹⁶

Diagnosis

Diagnosis may be suspected by taking a thorough history and physical examination. Typically there is a strong family history with the exception of those individuals who develop a spontaneous mutation later in life. Screening is performed by analysis of C4 levels, which are significantly reduced in HAE. In type I HAE, there is a quantitative decrease in serum C1-INH levels that are also functionally abnormal, whereas in type II HAE there is a normal or often elevated serum level of C1-INH but functionally reduced C1-INH activity.

Patients with type III HAE have normal quantitative and functional levels of C1-INH, but a strong family history of angioedema. This condition has been associated with a gain of function mutation in factor XII in some patients.

Genetic analysis can aid in prenatal diagnosis. However, in general, genetic studies are not required or necessary to make a diagnosis of HAE, as history, physical examination, and complement studies usually suffice. In the absence of a clear family history, up to 25% of HAE patients can have a spontaneous mutation but in these cases acquired angioedema should be excluded by obtaining a C1q complement component.

Treatment

Standard treatments for other types of angioedema, including epinephrine, corticosteroids, and H1 or H2 histamine receptor antagonists, are ineffective for HAE.¹⁷ Traditional therapies for HAE, including fresh frozen plasma (FFP), ϵ -aminocaproic acid, and danazol, may be efficacious but have a negative safety profile.¹ Drugs currently under investigation or recently approved to treat HAE in the US can be

divided into three categories: C1-INH replacement therapies; a kallikrein inhibitor and a bradykinin receptor 2 antagonist. The C1-INH replacement therapies can be further subdivided into plasma-derived products, which include Berinert P (CSL Behring) and Cinryze[®] (Viropharma) and a recombinant human C1-INH, conestat alfa (Rhucin[®] in US, Ruconest[®] in Europe; Pharming). Ecallantide (Kalbitor[®]; Dyax Corporation) is a kallikrein inhibitor and icatibant (Firzyr[®]; Shire Pharmaceuticals) is a bradykinin receptor antagonist. Treatment of HAE includes: long-term prophylaxis with androgens (ie, danazol) or Cinryze and on-demand therapy with Berinert P, ecallantide and, when approved in the US, icatibant and conestat alfa.

Acute “on-demand” treatment

Traditionally, acute therapy for HAE in the US consisted of FFP, antifibrinolytics or high-dose androgens. As mentioned, drawbacks of using FFP include potential infection transmission and worsening of acute symptoms after administration. For ϵ -aminocaproic acid there is only anecdotal evidence of its efficacy for acute attacks. The European experience with tranexamic acid is more robust but this agent is not readily available in the US for treatment of acute HAE attacks. Attenuated androgens are ineffective for acute treatment because their therapeutic effects are delayed for at least 1 to 2 days after they are started.^{1,18,36,37}

Recently Berinert P and ecallantide have been approved for use of acute attack therapy in the US.

Short-term prophylaxis

Short-term prophylaxis for HAE should be initiated before any planned invasive procedure, including dental procedures if the patient has a history of swelling with trauma. Administration of FFP prophylaxis before trauma has been shown to decrease the risk of attack.^{33,34} Recently, a case involving a 51-year-old man with HAE who received Cinryze 1 hour before mitral valve reconstruction surgery requiring a cardiopulmonary bypass pump was reported. This case represented the first successful use of C1-INH as acute and prophylactic therapy in the US for a patient undergoing cardiac surgery requiring a cardiopulmonary bypass pump.³⁵

Long-term prophylaxis

In patients with more than one attack a month or with a history of life-threatening laryngeal attacks, long-term prophylaxis should be considered.¹¹

Specific treatments

Avoidance of triggers

Trauma, stress, infections, ACE inhibitors, and hormone replacement therapy has been associated with angioedema attacks and should be avoided if possible in HAE patients.^{3,5,18,19} However, many patients with HAE have no recognizable triggers and no pre-aura that would indicate an eminent attack.

Attenuated androgens

Multiple studies demonstrate efficacy of androgens as long-term prophylaxis for HAE.^{9,20-22} These drugs are synthetic 17- α -alkylated androgens and include danazol, stanozolol, and oxandrolone.^{6,7} Originally thought to be effective by increasing hepatic synthesis of C1-INH, they have been shown to be effective for type II and type III HAE as well.^{9,20,23,24} Androgens have significant, common side effects including weight gain, menstrual irregularities, virilization, headache, myalgia, depression, acne, elevated liver function tests and cholesterol, and fatty liver. Other serious adverse events include myocardial infarction, stroke, acute pancreatitis, biliary hamartoma, liver cell adenoma, and hypertension.^{6,20,22,25}

Antifibrinolytics

The antifibrinolytics, which include ϵ -aminocaproic acid and tranexamic acid, are considered to be less effective for long-term prophylaxis than attenuated androgens but have been demonstrated to be effective for acute attacks.^{1,26,27} The mechanism of action of antifibrinolytics is not well understood. Traditionally, they were used in situations when avoidance of attenuated androgen side effects was important, particularly in children.²⁸ Major adverse effects include thrombosis and rhabdomyolysis.^{29,30}

Fresh frozen plasma

FFP has been used successfully for acute HAE attacks but there is increased risk of infection transmission and in some cases a paradoxical worsening of HAE has been observed.

Cinryze

The plasma-derived C1-INH replacement product, Cinryze, was approved in the US in 2008 for routine prophylaxis in adolescent and adult patients. It is produced by Viropharma, Inc. (Exton, PA) in partnership with the Sanguin Blood Supply Foundation. Sanguin produces a similar product known as Ceter[®], which has been on the market in the Netherlands for 11 years. Cinryze is unique in that it is

pasteurized and nanofiltered C1-INH from pooled plasma of US donors. The nanofiltration step offers protection against nonenveloped viruses and prions.^{31,32} It is dosed twice weekly for long-term prophylaxis. To date, the only C1-INH replacement product approved for prophylactic use of HAE in the US is Cinryze.

Berinert P

Berinert P was approved in 2009 in the US to treat acute abdominal and facial attacks in adolescents and adults and is currently approved in 28 countries worldwide.³⁸ It is a purified human C1-INH, prepared by CSL Behring (Marburg, Germany) from the pooled plasma of US donors. There are also published reports demonstrating effectiveness of long-term prophylaxis with Berinert P.³⁹ Berinert P is considered very safe to use and is administered intravenously.

Ecallantide

Ecallantide was approved in 2009 in the US to treat acute peripheral, abdominal, and laryngeal attacks in patients ≥ 16 years old (it is currently awaiting approval in Europe).⁴⁰ It is manufactured by Dyax (Cambridge, MA). The drug inhibits plasma kallikrein, a serine protease involved in the breakdown of high-molecular-weight kininogen to bradykinin, and is an even more potent and selective inhibitor of kallikrein than C1-INH.⁴¹ It is a recombinant product and therefore free of human or animal contaminants. It is administered via subcutaneous injections.⁴² Ecallantide is well tolerated but has been associated with a 3.9% incidence of anaphylaxis during clinical trials. For this reason, an immunogenicity trial is to determine the ongoing risk of developing specific IgG and IgE antibodies and anaphylaxis with repeated use.⁴³

Experimental therapies for HAE

New therapies, icatibant and conestat alfa, are under consideration for FDA approval for use in the US but have been approved for use in Europe. There continues to be a need for further investigation into both acute, short-term and long-term prophylactic treatment of HAE as well as other potential indications for these agents. For example, despite long-term prophylaxis, breakthrough angioedema attacks still occur in a significant number of patients. This has led to a dose escalating trial for Cinryze to determine the maximum safe dose required to prevent breakthrough attacks. In addition, the potential adverse effects of approved treatments (ie, anaphylaxis reports with ecallantide) have significantly limited their use.⁴⁴

Icatibant

Clinical trials have now been completed for Icatibant in the US and it is awaiting FDA approval however, it is currently available in several European countries.⁴⁵ It is manufactured by the German company Jerini (Berlin, Germany). The drug is a synthetic decapeptide, similar in structure to bradykinin, which functions as a highly specific and extremely potent antagonist of the bradykinin receptor, BK2R. Icatibant is resistant to the proteolytic effects of carboxypeptidase-N and angiotensin converting enzyme, which degrade bradykinin.⁴⁶ It is delivered in a subcutaneous form.

Conestat alfa

Introduction to the drug

Over the last decade the management of HAE has been dramatically changing. Biotechnical advances have allowed the emergence of numerous C1-INH replacement options that expand the ability to individualize treatment. Human C1-INH is a plasma serine protease inhibitor that inhibits proteases in the coagulation/fibrinolytic system (factor XII, factor XI, thrombin, plasmin, and tissue plasminogen activator), the complement system (C1r, C1s, MASP-1, and MASP-2), and the kinin system (kallikrein) (Figure 1).⁴⁷ Plasma-derived C1-INH has been used to treat acute HAE attacks since the 1970s and has dramatically improved the outcome of laryngeal attacks in these patients in countries where it has been readily available.^{48,49} In 1996, the first double-blind, placebo-controlled trials documenting the efficacy of C1-INH replacement in both acute attacks and prophylaxis were reported.³⁹ Attempts to clone C1-INH in multiple cellular expression systems has resulted in severe alterations in its

protein expression or conformation.^{50–53} In order to address the need for a readily available supply of C1-INH that was not dependent on plasma donations, the Dutch company Pharming (Leiden, the Netherlands) developed conestat alfa, a recombinant human C1-INH made from the breast milk of transgenic rabbits. Conestat alfa is being marketed under the brand name Rhucin in the US and Ruconest in Europe. The production techniques utilized to make conestat alfa have resulted in a highly purified, large quantity of functionally active product with extremely low risk of pathogen transmission. The drug has a purity level of 99.98%, with <20 ppm of contaminants. Phase I, II, and III clinical trials have now been completed in Europe and the US. It has been approved in Europe under the name Ruconest, but approval in the US under the name Rhucin is still pending the results of a supplemental clinical trial currently in progress.⁵⁴

Biochemical structure and function

The C1-INH gene is on chromosome 11 and consists of 8 exons and 7 introns. The protein consists of 500 amino acids.⁵⁵ C1-INH exists in plasma as a heavily glycosylated single-chain protein of 478 amino acids and weighs 105 kDa, of which approximately 50% is carbohydrate. Conestat alfa is a human plasma protease C1-INH, recombinant protein expressed in the mammary gland of transgenic rabbits, also consisting of 478 amino acids, though it weighs less (67,000 kDa) than human C1-INH due to less glycosylation.⁵⁶ The N-glycans of conestat alfa are under-sialylated, whereas its O-glycans are over-sialylated.⁵⁷ Functionally, conestat alfa, compared with human C1-INH, is similar in its ability to inhibit C1, plasma kallikrein, factor XIa, and factor XIIIa. Though it appears that differential glycosylation of conestat alfa relative to the human protein decreases the half-life to approximately 3 hours, this does not seem to be relevant clinically.² Since N-linked glycosylation is important for the three-dimensional structure of protein, this process was studied in conestat alfa. It was demonstrated that the major N-glycan structures on conestat alfa were similar to those of human C1-INH, but sialylation levels decreased with progression of lactation.⁵⁸

Pharmacology

Because C1-INH is the only known inhibitor of the classical arm of the complement pathway, in HAE, replacement of C1-INH decreases the baseline consumption of C4 in asymptomatic patients (Table 1). Hence, the pharmacodynamics of conestat alfa were analyzed by measuring C4 concentration and degradation in asymptomatic HAE patients. Conestat alfa exhibited dose-dependent activity both by increasing

Figure 1 Sites of C1-inhibitor (C1-INH) regulation of the contact, complement, and fibrinolytic systems. Conestat alfa, a recombinant C1-INH, likely regulates the same sites.

Table 1 Pharmacodynamics of C4 in asymptomatic hereditary angioedema patients

	Baseline serum concentration	Maximum concentration (C _{max} , %)	Time of maximum concentration (T _{max} , mins)	Minimum concentration (C _{min} , %)	Time of minimum concentration (T _{min} , mins)
C4	538.7 (184.37)	175.5 (81.93)	640.0 (123.94)	80.0 (2.05)	35.5 (20.11)
C4b/c	107.4 (58.51)	5.3 (1.90)	40.3 (39.63)		

C4 levels and decreasing C4b/c. During HAE attacks, the C4 level peaked at 24 hours and continued to be elevated out to Day 22.⁵⁹ Pharmacokinetic analysis revealed that C1-INH levels were elevated to twice normal levels for 2 hours and remained greater than the critical activation level of 0.4 U/mL for approximately 9 hours (Table 2).⁶⁰ With doses ranging from 6.25 U/kg–100 U/kg of conestat alfa in asymptomatic patients, both maximum function of C1-INH (C_{max}) and the duration of C1-INH serum level above 0.4 U/mL exhibited a dose-dependent increase, with ranges of 0.32 U/mL–2.46 U/mL and 9.1–549.7 min, respectively. During attacks in which patients were treated with 100 U/kg of conestat alfa, the C_{max} was 3.8 ± 0.8 U/mL versus 2.5 ± 0.2 U/mL in asymptomatic patients treated with the same dose.⁶¹ The dose-normalized C_{max} was constant ($P = 0.48$), suggesting dose proportionality, but clearance ranged from 71.4 to 12.7 mL/min and the elimination half-life ranged from 28 to 172 minutes depending on the dose. The pharmacokinetic data fit a 1-compartment model based on Michaelis–Menten kinetics and demonstrated dose independence for maximum enzymatic activity (V_{max}), which is 45 U/minute, and the volume of distribution, which is 3.3 L. The Michaelis–Menten constant is 0.57 U/mL.⁶²

Conestat alfa is freeze-dried and free of preservatives. One unit corresponds to the quantity of C1-INH present in 1 mL of normal fresh plasma. Conestat alfa contains 2100 units per vial after reconstitution in 14 mL of diluent and is administered intravenously. The maximum dose is 4200 U for patients with body weight ≥84 kg. It is recommended that no more than two intravenous injections be administered within any 24-hour period.

Safety

No drug-related adverse events or clinically relevant vital sign changes, ECG findings, or laboratory abnormalities

(including hematological, biochemical, and coagulation, viral serology, and anti-C1-INH and antibodies against rabbit milk protein) have been reported in clinical trials. The most common side effect is headache.

Blood samples from 137 HAE patients with a total of 322 treatments with conestat alfa for acute HAE attacks were tested for infectious transmission and antibodies in clinical studies. Fourteen patients had received conestat alfa for at least five acute angioedema attacks with up to 20 treatments in one patient.⁶³ Transmission of rabbit or human viruses have not been observed.^{61,62,64}

The frequency and amplitude of anti-conestat alfa IgG and IgM results in pretreatment versus post-treatment samples was similar, suggesting no effect of antibody generation with treatment. Positive samples did not have any detectable neutralizing antibodies. For possible antibody formation against host-related impurities (HRI), positive anti-HRI results were slightly higher for postexposure samples, but with repeated treatment there were no clinically relevant adverse events in these patients. In addition, these anti-HRI responses did not persist.

One hundred thirty-seven healthy volunteers and HAE patients were tested for the presence of IgE antibodies against four rabbit allergens and 10 other animal allergens after their last exposure to conestat alfa. Twenty-four out of 137 (17.5%) subjects had at least one positive IgE antibody test result at baseline. Five subjects had a positive test against rabbit allergens. Three of the five subjects positive for IgE against rabbit allergens reported allergic symptoms after conestat alfa exposure.⁶⁵ One healthy volunteer, who did not disclose a history of rabbit allergy and with the highest rabbit dander-specific IgE level (39 kU/L), had an anaphylactic reaction after the first exposure to conestat alfa. This has been the only severe allergic reaction to date.^{2,62,65,66} Three subjects

Table 2 Pharmacokinetics of conestat alfa

Baseline serum C1-INH concentration (U/mL)	Maximum concentration (C _{max} , U/mL)	Dose normalized maximum concentration (U/mL/U/kg)	Time above critical concentration of 0.4 U/mL (min)	Clearance (mL/min)	Volume of distribution (L)	Half-life (min)	Maximum enzymatic activity (V _{max})
0.18 (0.12)	1.36 (0.31)	0.0236 (0.00468)	314.5 (210.3)	22.8 (7.3)	3.03 (0.79)	93.7 (8.5)	46.9 (14.97)

had pre-existing IgE against cow milk, but none developed allergic-type symptoms on exposure to milk-derived conestat alfa. After treatment, none of the 24 subjects with pre-existing IgE had an increase in IgE levels to rabbit or cow milk allergens. One subject after exposure developed IgE against cow milk allergens, but not against rabbit allergens. Another subject developed IgE against rabbit meat. Neither of these two subjects developed allergic symptoms with conestat alfa exposure.⁶⁵ Excluding antirabbit IgE in patients is advised before use of conestat alfa.

Efficacy

In two open-label, clinical studies on nine HAE patients who were treated with conestat alfa for 13 angioedema attacks, symptoms of attacks were assessed both by the physician and by the patients using visual analog scales (VAS, Table 3). These studies demonstrated that the median time to onset of symptom relief was <60 minutes, whereas median time to minimal symptoms was <8 hours.⁶¹ VAS scores for symptoms of peripheral attacks were obtained from 65 patients in all clinical trials. Treatment with conestat alfa significantly decreased the duration of swelling, pain and associated dysfunction of peripheral angioedema attacks in HAE patients.⁶⁷

Two separate randomized, double blind, placebo-controlled clinical trials showed median time to the beginning of symptom relief and median time to minimal symptoms was significantly improved with conestat alfa. Patients were randomized to receive conestat alfa 100 U/kg, 50 U/kg, or placebo. For the 100 U/kg, 50 U/kg, and placebo doses, patients reported onset of symptom relief at a median of 68 minutes, 122 minutes, and 258 minutes, respectively and time to minimal clinical symptoms of 245, 247, and 1098 minutes, respectively. These results were statistically significant relative to placebo with *P* values <0.01.^{64,68} All attacks treated with conestat alfa abated, without evidence

of acute recurrence or rebound, defined as an increase in the VAS to the patient's baseline score or greater after experiencing some relief within 4 hours after receiving the drug.⁶⁴

To obtain further evidence about the safety and efficacy of conestat alfa, particularly with repeated dosing for recurrent attacks, open-label extensions were included as a part of the randomized studies. Sixty-five patients were treated with conestat alfa doses ranging from 2100 U to 100 U/kg. The median time to onset of relief and median time to minimal symptoms was similar to the randomized trial results. Of note, treatment was effective independent of the anatomical location. Although all doses of conestat alfa used in the open-label extensions were effective, the 2100 U dose appeared to be less effective.^{67,68}

Conestat alfa appears to be safe with no reduction in effectiveness in patients receiving up to 26 treatments. Therapeutic failure, defined as time to onset of relief occurring after 4 hours, relapse within 4 hours, or the use of additional medication to treat the attack was reported in 11% and 10% of attacks treated with 50 and 100 U/kg, respectively, compared with 17% for the 2100 U dose.⁶⁸ The percentage of HAE attacks responding to 50 U/kg and 100 U/kg doses of conestat alfa within 4 hours was 92% and 93%, respectively, compared with 41% with placebo. Thus there appears to be no significant difference between the 50 U/kg and 100 U/kg doses. In addition, a computer simulation with a population pharmacokinetic model based on data from 214 administrations of conestat alfa in 120 patients demonstrated that doses of 50 U/kg brought functional C1-INH levels into normal range (>0.7 U/mL) in almost all patients and above the critical activation level (0.4 U/mL) in all patients.⁶⁸ Therefore, since no further improvement was achieved with a dose of 100 U/kg, the 50 U/kg dose is the recommended dose for the treatment of acute HAE attacks with conestat alfa.

Table 3 Summary of safety and efficacy trials

	Treatment doses	Subjects	Efficacy results			Safety results
Phase II	100 U/kg within 8 hours of attack onset	9 subjects with	80% achieved symptom relief in 2 hours and minimal			No drug-related adverse events or immunogenic reactions
		13 severe attacks	symptoms by 12 hours			
Phase III	Saline	n = 29	Time to symptom relief (min)	Time to minimal symptoms (min)	Treatment failure	No postexposure antibody response against either rhC1-INH or rabbit-related impurities
	50 U/kg	n = 12	495	1220	59%	
	100 U/kg	n = 29	122	247	0%	
			66	266	10%*	

Note: *The larger 95% CI of the odds ratios for the 50 U/kg group compared with that for the 100 U/kg group suggests no real difference in the percentage of therapeutic failures in either treatment group, which is in agreement with open label data.

Current commercial status

Conestat alfa has been approved by the European Medicines Agency and is now available in several European countries. The FDA has delayed its approval in the US as it felt that additional therapeutic and safety analyses were necessary, which are currently ongoing.

Conclusion

In the past few years multiple C1-INH replacement products have been approved for the treatment of both acute HAE attacks and long-term prophylaxis. Conestat alfa is unique from other products as it is being produced from transgenic rabbits, which can provide a potentially unlimited source drug, which obviates the need for collecting plasma or any concerns about infectious transmission from human donors. In summary, the clinical trials to date demonstrate that conestat alfa is safe and effective for treatment of HAE attacks, independent of the anatomic location. Symptoms quickly respond (1 hour vs 8 hours) and resolve (6 hours vs 20 hours) with treatment. Unless there was a prior sensitization to rabbit allergens, no significant adverse events such as anaphylaxis have been reported. There were no laboratory abnormalities and no acute relapses or rebound attacks observed. The dose of 50 U/kg appears to be the lowest effective dose for treatment. No additional therapeutic benefit has been observed by using higher doses. Finally, no decrease in effect has been reported with repeated doses.

Conestat alfa appears to have the same biologic and clinical effect as human C1-INH. Because C1-INH concentrate is safe and effective for pediatric and pregnant patients,⁶⁹ given the similar biological profile of conestat alfa to its human counterpart, it would also likely be safe and effective for these populations, but additional studies to confirm these indications have yet to be done.

In that plasma-derived C1-INH has been investigated as a therapy for indications other than HAE such as sepsis, acute myocardial infarction, cardiopulmonary bypass surgery, and ACE-inhibitor induced angioedema, further investigations are warranted to determine whether conestat alfa would also be effective for these indications.^{70–73}

Therapeutics and Clinical Risk Management

Publish your work in this journal

Therapeutics and Clinical Risk Management is an international, peer-reviewed journal of clinical therapeutics and risk management, focusing on concise rapid reporting of clinical studies in all therapeutic areas, outcomes, safety, and programs for the effective, safe, and sustained use of medicines. This journal is indexed on PubMed Central, CAS,

Submit your manuscript here: <http://www.dovepress.com/therapeutics-and-clinical-risk-management-journal>

EMBASE, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
