Abstract: Splanchnic vein thrombosis (SVT) including portal, mesenteric, splenic vein thrombosis and the Budd-Chiari syndrome, is a manifestation of unusual site venous thromboembolism. SVT presents with a lower incidence than deep vein thrombosis of the lower limbs and pulmonary embolism, with portal vein thrombosis and Budd-Chiari syndrome being respectively the most and the least common presentations of SVT. SVT is classified as provoked if secondary to a local or systemic risk factor, or unprovoked if the causative trigger cannot be identified. Diagnostic evaluation is often affected by the lack of specificity of clinical manifestations: the presence of one or more risk factors in a patient with a high clinical suspicion may suggest the execution of diagnostic tests. Doppler ultrasonography represents the first line diagnostic tool because of its accuracy and wide availability. Further investigations, such as computed tomography and magnetic resonance angiography, should be executed in case of suspected thrombosis of the mesenteric veins, suspicion of SVT-related complications, or to complete information after Doppler ultrasonography. Once SVT diagnosis is established, a careful patient evaluation should be performed in order to assess the risks and benefits of the anticoagulant therapy and to drive the optimal treatment intensity. Due to the low quality and large heterogeneity of published data, guidance documents and expert opinion could direct therapeutic decision, suggesting which patients to treat, which anticoagulant to use and the duration of treatment.

Keywords: Budd-Chiari syndrome, mesenteric vein thrombosis, portal vein thrombosis, splanchnic vein thrombosis, splenic vein thrombosis

Introduction

Splanchnic vein thrombosis (SVT) refers to thrombosis occurring in the splanchnic venous circulation, which drains the digestive system from the lower oesophagus to the upper two-thirds of the rectum.¹ SVT encompasses portal vein thrombosis (PVT), mesenteric veins thrombosis (MVT), splenic vein thrombosis and the Budd-Chiari syndrome (BCS). The BCS includes any obstruction of the hepatic venous outflow located between the small hepatic venules and the confluence of the inferior vena cava into the right atrium.² Thrombosis of the extrahepatic portal axis with possible extension to other splanchnic veins is sometimes referred under the term extrahepatic portal vein obstruction (EHPVO), although EHPVO can also include other mechanisms of portal vein obstruction (e.g. neoplastic infiltration).^{2,3}

Epidemiology

SVT is an unusual manifestation of venous thromboembolism (VTE). While usual site VTE, i.e. deep vein thrombosis of the lower limbs and pulmonary embolism, occur in about 70–270 cases per 100,000 person-years,⁴ the incidence of SVT is at least 25 times lower. Furthermore, a high variability in the incidence of SVT has

been reported which may depend on the type of data source, differences in diagnostic tests, site or type of SVT -incidental or symptomatic- considered.⁵

PVT is the most frequent type of SVT. A prevalence of 1.0% was reported in a large population study evaluating more than 23,000 consecutive autopsies,⁶ while an incidence of 3.7 cases per 100,000 person-years was reported in a large multicentre Swedish study.⁷

BCS is the least common manifestation of SVT, with reported incidence rates of around 1–2 cases per million inhabitants per year.^{8,9} The estimated prevalence of BCS varies across different countries, ranging from around 1–4 cases per million inhabitants in the West^{10,11} up to 5–7 cases per million inhabitants in the East.^{12,13}

Age and sex distribution of SVT is heterogeneous, with some differences based on the site of thrombosis. Patients with BCS tend to be the youngest especially in Asian countries, where incidence peaks between 20 and 40 years.^{14,15} Although this difference is less pronounced in Western countries, BCS patients are still approximately one decade younger than PVT patients (for instance 50 vs 61 years, or 45 vs 54 years, respectively, in the Italian and US cohorts).^{9,16} Conversely, the incidence of MVT is higher around 70–79 years.^{17,18}

Approximately two thirds of SVT patients are men.^{9,16,19} Recent data from hospital admissions in North-western Italy documented an annual incidence of PVT of 3.78 and 1.73 cases per 100,000 inhabitants in men and women, respectively.⁹ BCS showed a predominance of women (52–69%) in Western studies,^{11,20} whereas a slight predominance of men was reported in Asian studies.^{12,13} This finding can reflect the different pathogenesis of BCS, being hormonal factors more frequent in the West and membranous web obstruction in the East.²

Risk Factors

Identification of the causative trigger allows the classification of SVT as provoked or unprovoked, based on the presence or absence of a local or systemic risk factor (Table 1).²¹ The variable prevalence of risk factors among patients with SVT may be explained by differences in study populations. In unselected cohorts of SVT patients, the major risk factors are liver cirrhosis and solid cancer, each responsible for about 25% of cases, while unprovoked SVT represents 15% to 27% of all SVTs.^{16,19}

Cirrhotic patients present both a pro-coagulant status and portal axis hemodynamic alterations which may favour the occurrence of SVT. Recent data showed that patients with liver cirrhosis are not naturally “anticoagulated” as previously believed, and may be at increased risk of thrombosis due to an acquired pro-thrombotic status related to high factor VIII/protein C ratio, increased thrombin generation, and alteration in fibrin clot structure.^{22–24} Additionally, reduced portal flow can contribute to PVT development.²⁵ Results of clinical studies confirmed these experimental data showing an increased VTE risk and a prevalence of PVT of about 10% in cirrhotic patients.^{26–28}

The association between solid cancer and VTE can be explained by cancer-related haemostatic system alterations and other risk factors frequently associated with cancer, such as immobilization, surgery, chemotherapy, and central venous catheter.^{29–32} The prevalence of cancer-related SVT is low in outpatients (about 1%),³³ with liver (26%) and pancreatic (11%) cancers being the most common neoplasms.³⁴ Furthermore, 15% of patients with SVT receive a diagnosis of solid cancer after a median follow-up of 1.6 years,³⁴ suggesting that, as usual sites VTE,³⁵ SVT may be an early marker of cancer.

Table 1 Risk Factors For Splanchnic Vein Thrombosis

Risk Factors For SVT		
Persistent Acquired Risk Factors	Transient Acquired Risk Factors	Inherited Risk Factors
Liver cirrhosis Solid cancer Myeloproliferative neoplasm Inflammatory bowel disease Antiphospholipid syndrome Other hematologic disease (e.g. PNH) Autoimmune disease (e.g. Behçet's disease)	Intra-abdominal Inflammations/infections Abdominal surgery Hormonal therapy Pregnancy or puerperium	Factor V Leiden mutation Prothrombin G20210A mutation JAK2V617F mutation Protein C deficiency Protein S deficiency Antithrombin deficiency

Abbreviations: PNH, paroxysmal nocturnal haemoglobinuria; SVT, splanchnic vein thrombosis.

Patients with myeloproliferative neoplasms (MPN) show an increased risk for both arterial and venous thrombosis.^{36,37} The incidence of SVT is higher in MPN (from 1% to about 20%)³⁸ than in the general population,²¹ and about 10% of all SVT are MPN-related.^{16,19} The pathogenesis of thrombosis in MPN is a complex and multifactorial process involving quantitative and qualitative alterations of platelet, erythrocytes, leukocytes, and endothelial cells.³⁶ The V617F substitution of the Janus Kinase 2 (JAK2) gene showed a strong association with MPN and SVT.^{39,40} The prevalence of JAK2V617F mutation is higher in SVT (32.7%) compared with usual sites VTE (0.88%), cerebral vein thrombosis (2.57%) or retinal vein occlusion (0.99%).^{19,41} Furthermore, this mutation was found in 94.7% of patients with unusual site thrombosis (cerebral and SVT) and overt MPN.⁴⁰ From a pathophysiologic point of view, the JAK2V617F mutation seems to promote thrombosis through P-selectin overexpression leading to platelet aggregation and fibrin deposition.^{42,43}

Hormonal therapy, abdominal surgery (e.g. splenectomy, liver transplantation and bariatric surgery), inflammatory bowel diseases (Crohn's disease and ulcerative colitis), pregnancy or puerperium are responsible for the majority of the remaining cases of SVT.^{16,19} Furthermore, intra-abdominal infections (e.g. diverticulitis, appendicitis, pancreatitis) due to anaerobes, aerobic bacteria or fungi may cause pylephlebitis.⁴⁴ Other rare causes of SVT are paroxysmal nocturnal hemoglobinuria and Behçet's disease.²¹

Thrombophilia may be an additional risk factor, although low levels of anticoagulant proteins are generally related to an impaired liver production.⁴⁵ The prevalence of significant thrombophilia (mainly factor V Leiden, prothrombin G20210A, and JAK2V617F mutations) is higher in SVT (12.3%) than usual site VTE (8.5%).⁴⁶ In particular, BCS, MVT and multiple veins thrombosis show the highest rate of pro-thrombotic alterations.^{19,46} Finally, one third of patients with SVT present with more than one risk factor, reflecting the multifactorial aetiology of SVT.⁴⁷

Specific venous involvement in SVT shows some peculiarities based on the associated risk factors. While about 90% of cirrhosis-related SVT involve the portal vein,⁴⁸ cancer-related SVT involves the portal, splenic, and superior mesenteric veins in 48%, 42%, and 21% of cases, respectively.⁴⁹ In patients with MPN, PVT is the most common type of SVT (about 60%);⁵⁰ however, the prevalence of BCS is higher in MPN patients (approximately 17% of MPN-related SVT are BCS,⁵⁰ while <10% of BCS

were reported among all SVT).^{16,19} Nearly half of patients with pancreatitis show splenic vein involvement.¹⁶ Multiple vessels thrombosis is reported in approximately a fifth of patients with cancer (24%), cirrhosis (22%), and MPN (17%).¹⁶

Clinical Presentation

Clinical manifestations of SVT are nonspecific. The most common symptom is abdominal pain, reported in approximately half of SVT patients, followed by gastrointestinal bleeding and ascites.^{16,19} Other nonspecific symptoms are nausea, vomiting, anorexia, diarrhoea or constipation, and fever. In up to one third of patients, SVT can be asymptomatic or incidentally detected during abdominal imaging performed for other reasons, such as follow-up of cancer or cirrhosis.^{51,52} However, each site of thrombosis can manifest with a specific clinical scenario.²¹

Portal Vein Thrombosis

PVT can be acute or chronic.⁵³ Acute PVT is characterised by the sudden onset of abdominal pain, whereas signs of portal hypertension (such as hypersplenism, ascites, oesophageal varices, and the presence of portal cavernoma or other porto-systemic collateral veins on imaging) are typical manifestations of chronic PVT.

Mesenteric Vein Thrombosis

MVT can present an acute, subacute or chronic course.⁵⁴ Acute MVT is characterised by the sudden onset of abdominal pain and is complicated by intestinal infarction in one third of patients.¹⁷ Abdominal pain lasting for several days without intestinal infarction is more typical of subacute MVT, while signs of portal hypertension identify chronic MVT.⁵⁴ MVT has a 30-day mortality rate of 20%, mainly due to bowel infarction.¹⁷

Splenic Vein Thrombosis

Data on isolated splenic vein thrombosis are scarce. The most common symptom is abdominal pain, reported in 57% of patients, followed by gastrointestinal bleeding (29%) and nausea (23%).¹⁶ Up to 17% of patients can be asymptomatic.¹⁶

Budd-Chiari Syndrome

BCS can be fulminant, acute, subacute or chronic.⁵³ Patients with BCS typically present with a triad of abdominal pain, ascites, and hepatomegaly. In fulminant BCS, the rapid onset of hepatocellular necrosis may lead to

acute liver failure within few days, while chronic BCS generally presents with signs of portal hypertension.⁵⁵

Diagnosis

The diagnosis of SVT relies on imaging. D-dimer, a well-known biomarker for deep vein thrombosis and pulmonary embolism, has limited utility in this setting. Although some studies showed that mean D-dimer values are increased in SVT patients,^{56,57} D-dimer can also be elevated in other conditions, such as liver cirrhosis or hepatocellular carcinoma, which reduces its diagnostic predictive value.⁵⁸ Recent data suggested that D-dimer levels may predict the development of multi-organ dysfunction and short-bowel syndrome after acute MVT.⁵⁹

Angiography was the gold standard for SVT diagnosis, but it is an invasive examination and rarely performed nowadays. Doppler ultrasonography (DUS) has become the first line diagnostic test with a sensitivity of 89-93% and a specificity of 92-99% for PVT.⁶⁰ DUS is also very accurate for BCS since it can directly visualise the intra- and supra-hepatic veins and the inferior vena cava, the typical intrahepatic collaterals, and the texture of the liver parenchyma.⁶¹ The sensitivity of DUS is lower for the mesenteric veins, due to the bowel gas which can interfere with their visualisation,⁶² and for the splenic vein, due to the presence of several collaterals near the splenic hilum.⁶³

Computed tomography (CT) angiography and magnetic resonance (MR) angiography are nowadays the standard imaging for MVT, since they can better visualise the mesenteric veins and show signs of intestinal infarction.⁶⁴ They can also be used in patients with suspected PVT or BCS, when the DUS is not diagnostic or to complete information from DUS.⁶⁵ CT angiography is faster and widely available, but involves ionizing radiations and the iodinated contrast agent can cause allergic reactions or renal toxicity. MR angiography is used for patients with contraindications to CT angiography, since the scanning time is longer (30–60 mins) and has lower spatial resolution.⁶⁰ Liver biopsy is usually not needed, except to confirm rare forms of BCS involving only the small intrahepatic veins or to exclude other hepatic disorders, such as the veno-occlusive disease.^{65,66}

Distinguishing acute or recent PVT from chronic PVT represents a difficult but relevant challenge with therapeutic implications. Acute PVT is visualised as hyperechoic material into an enlarged vein with partial or total absence of vascular flow on DUS or as hyperattenuating material

without luminal contrast enhancement on CT. Portal cavernoma, easily detected by both DUS and CT, is the main sign of chronic thrombosis and is defined as the presence of multiple small collaterals around the PVT.^{67,68} In doubtful cases, the clinical presentation, the absence of collateral circulation, and the absence of SVT in previous exams could help establishing the diagnosis of acute/recent SVT.⁶⁸

Treatment

During the last few years, a large number of observational studies tried to evaluate the safety and efficacy of anticoagulant treatment in patients with SVT. The paucity and variability of available data in terms of type, dose, and duration of anticoagulant therapy can be explained by the relative rarity, extreme clinical variability, and challenging diagnostic evaluation of SVT. All these aspects may have contributed to the heterogenous level of evidence and grade of recommendations in published guidelines.^{2,3,69–71} Furthermore, “real world” patients are often more complex compared to the typical cases considered by the guidelines and require a careful evaluation of the risk-to-benefit balance of the anticoagulant treatment.

Pre-Treatment Evaluation

Before starting anticoagulant treatment, physicians need to carefully evaluate the bleeding risk which is mainly related to portal hypertension complications, such as ascites, varices, or gastro-intestinal bleeding at clinical presentation.^{68,72,73} The presence of oesophageal varices is an independent risk factor for major bleeding,^{72,73} thus an upper endoscopy to grade and eventually treat oesophageal varices should be considered before starting the anticoagulant therapy, especially in patients with liver cirrhosis and chronic SVT.^{21,68} The presence of oesophageal varices should not necessarily contraindicate or defer anticoagulant therapy which can improve the portal hypertension, as long as appropriate prophylactic measures are taken (beta-blockers or endoscopic treatment).⁶⁹ However, since endoscopic band ligation can require multiple sessions, in patients without active bleeding, an initial treatment with reduced or prophylactic doses of low molecular weight heparin (LMWH) could be considered.⁷⁴

Who Should Be Treated?

Treatment of acute SVT aims to achieve vessel recanalization and avoid complications, such as bowel ischemia or chronic portal hypertension.⁶⁷ Therefore, starting anticoagulant therapy in acute symptomatic SVT without absolute

contraindications is strongly recommended.^{2,3,69} Prevention of thrombosis progression or recurrence is the main goal of anticoagulant therapy in patients with chronic SVT, especially those with persistent risk factors. However, several areas of uncertainty still exist in the treatment of chronic SVT.^{67,75}

The 9th edition of the American College of Chest Physician (ACCP) guidelines strongly recommend anticoagulant therapy in symptomatic patients. Conversely, no treatment is suggested for incidentally detected SVT, possible exceptions being acute and extensive SVT, progression of previous known thrombosis, and ongoing chemotherapy in cancer patients.⁶⁹ Additional information on incidental SVT derived from the results of two recent large cohort studies. In the International Registry on SVT (IRSVT), the prognosis of incidentally detected SVT was comparable to symptomatic SVT,^{19,51} similarly to previous data on VTE at usual sites.⁷⁶ Although the use of anticoagulant treatment was significantly lower in patients with incidentally detected SVT (64%) compared with symptomatic patients (84%), the incidence of thrombotic events was not negligible. An overall incidence rate of thrombotic events 8.0 (95% CI, 5.2–12.1) and 7.0 (95% CI, 5.2–9.3) per 100 person-year was reported in incidentally detected and symptomatic SVT, respectively. In particular, untreated incidental SVT had an incidence rate of 11.5 events (95% CI, 6.2 to 21.3).⁵¹ Similar results came from the “Registro Informatizado Enfermedad Trombo Embólica” (RIETE) registry where patients with incidentally detected SVT presented a non-significantly higher rate of symptomatic recurrent VTE than those with symptomatic SVT.⁵²

Anticoagulant Choice

Several studies showed that early start of anticoagulation therapy (within one-two weeks from diagnosis) promotes better vessel recanalization compared to commencing later.^{77–79} Only one recent study found no correlation between early anticoagulant therapy and thrombosis recanalization possibly due to the use of vitamin K antagonists (VKA) without concomitant LMWH administration while reaching the target international normalised ratio (INR).⁸⁰

LMWH and VKA are the mainstay of the anticoagulant treatment for SVT (Table 2).^{2,3,69–71} Treatment is usually commenced with LMWH switching to VKA after a few days of overlapping treatment, once the INR is in the target range (2.0–3.0).⁶⁹ However, continuation of LMWH alone

may be preferred in cases of low platelet count, active cancer, or hepatic disease.⁶⁹

To date, only few but promising data are available on the direct oral anticoagulants (DOAC) for the treatment of SVT. In a recent small randomized controlled trial in 80 cirrhotic patients with PVT, rivaroxaban seemed more effective and safer compared with VKA.⁸¹ In a retrospective cohort of 50 cirrhotic patients with PVT treated with edoxaban or warfarin after an initial 2-week period with danaparoid sodium, edoxaban reduced recurrent VTE but increased the rate of major bleeding compared with VKA dose-adjusted to a lower INR target range (1.5–2.0).⁸² Finally, a small prospective observational cohort of patients with atypical site thrombosis including 26 SVTs, found similar rates of VTE recurrence and bleeding in patients treated with apixaban or rivaroxaban and those on enoxaparin.⁸³ While waiting for future data, clinicians should cautiously consider the use of DOACs for SVT, as they are still considered off-label in this group of patients. The same therapeutic schemes and dose modification as for usual site VTE could be applied with a careful clinical and laboratory follow-up.⁷⁴ However, all DOACs are contraindicated in patients with Child-Pugh class C, and rivaroxaban is contraindicated also in Child-Pugh class B. A number of ongoing studies is evaluating the use of the DOAC in SVT patients (NCT02627053, NCT02555111, NCT03193502, NCT03778502).

Concomitant medications and patient comorbidities (e.g. low platelet count, chronic liver disease, and moderate to severe renal failure) need to be carefully considered when deciding on the type and dose of anticoagulant treatment.^{2,69,84–88} Based on current available evidence on the treatment of patients with usual site VTE and expert opinions, our suggested approach to SVT patients with the above mentioned comorbidities is summarised in Table 3.^{21,84,85,89–93}

For How Long Should Patients Be Treated?

The recommended duration of anticoagulant therapy differs across guidelines (Table 2). The ACCP guidelines suggest 3 months of anticoagulant treatment in patients with a transient thrombotic risk factor and longer duration in those with a persistent thrombotic risk factor or unprovoked SVT and low bleeding risk.⁶⁹

Table 2 Guidelines Recommendations For The Anticoagulant Treatment Of Splanchnic Vein Thrombosis

AASLD 2009⁷¹				
Type Of Patients		Type Of Anticoagulation	Duration Of Anticoagulation	
EHPVO	Acute	LMWH → VKA (I,B)	Transient risk factor	At least 3 months ^c (I,B)

Notes: Recommendations from each guideline have been graded with different classifications. For additional information, please refer to individual guideline texts. ^cConsider long term anticoagulation in patients with thrombus extension into the mesenteric vein (IIa,C). ^{*}Consider anticoagulation if known prothrombotic condition or thrombosis of the superior mesenteric vein (after adequate prophylaxis for variceal bleeding). [§]Consider long term anticoagulation in case of known thrombophilia, personal or family history of VTE, intestinal ischemia. [°]Consider anticoagulation in patients with persistent risk factors. [°]Consider anticoagulant therapy in case of acute and extensive SVT, progression of previous known thrombosis, and ongoing chemotherapies in cancer patients. [#]Consider LMWH alone in case of active cancer, liver disease or thrombocytopenia. [§]Consider anticoagulant therapy in selected cases: candidates to liver transplantation with thrombosis of the main portal vein trunk or progressive PVT (3a;B), thrombosis extension to superior mesenteric vein (5,D) and strong prothrombotic conditions (5,D). ^{**}Consider lifelong anticoagulation in patients with superior mesenteric vein thrombosis, with a past history suggestive of intestinal ischemia or liver transplant candidates (C,2). Consider prolonging anticoagulation for some months and until transplant in liver transplant candidates once PVT has been repermeated (B,2).

Abbreviations: AASLD, American Association for the Study of Liver Diseases; ACCP, American College of Chest Physician; AISF, Italian Association for the Study of the Liver; BCS, Budd-Chiari syndrome; EASL, European Association for the Study of the Liver; EHPVO, extrahepatic portal vein obstruction; LMWH, low-molecular weight heparin; RF, risk factor; SVT, splanchnic vein thrombosis; VKA, vitamin K antagonist; VTE, venous thromboembolism.

The Baveno VI Consensus Workshop and the European Association for the Study of the Liver recommend at least six months of treatment for acute/recent SVT secondary to transient risk factors and long-term anticoagulation in case of persistent risk factors. Long-term anticoagulation should also be considered in patients with chronic SVT and a persistent pro-thrombotic state and in patients with transient risk factors who have a history of intestinal ischemia or recurrent thrombosis.^{2,3}

Confirming these data, a recent study showed an higher incidence of thrombotic events in patients with unprovoked SVT or SVT related to persistent risk factors such as liver cirrhosis, solid cancer, and MPN.¹⁹ Therefore, these categories of patients should be considered for long-term anticoagulation.

In addition, the American Association for the Study of Liver Diseases and the Report of the Baveno VI Consensus Workshop guidelines weakly recommend long-term anticoagulation for patients with thrombus extension into the mesenteric veins.^{3,71} Finally, long-term anticoagulant therapy should be administered to all patients with BCS, especially if unprovoked.³

Thrombus extension (partial versus total occlusion), involvement of multiple vessels, and lack of recanalization

during follow-up are all associated with worse prognosis and should be considered when deciding on treatment duration.²¹ Indeed, the dose and duration of the anticoagulant therapy was directed by the rate of vessel recanalization in several studies.^{68,94,95}

Our recommendations on the anticoagulant treatment in patients with SVT are summarized in Figure 1.

Thrombolysis

Only few studies evaluated the role of thrombolysis in SVT and reported conflicting results. Smalberg and colleagues showed that its effectiveness may be associated with a not negligible risk of bleeding.⁹⁶ In contrast, promising results were reported in another study involving patients with acute MVT.^{97,98}

The use of thrombolysis may be carefully considered in specialized centres for very selected cases (e.g. failure of anticoagulant therapy or MVT complicated by intestinal ischemia).⁷⁴

Budd-Chiari Syndrome

Due to the severity of BCS, anticoagulant treatment should be established as soon as possible and continued lifelong. Patients not-responsive to medical treatment should be managed

Table 3 Therapeutic Strategies For Patients With Splanchnic Vein Thrombosis And Thrombocytopenia, Kidney Failure Or Liver Cirrhosis

Comorbidity	Anticoagulant Therapy		
Thrombocytopenia	LMWH	VKA	DOAC*
PLT 50-149,000/ μ l	Therapeutic dose	Therapeutic dose (INR target range 2.0–3.0)	Therapeutic dose**
PLT 25-<50,000/ μ l	50% of therapeutic dose or prophylactic dose***	Not recommended, consider switch to LMWH	Not recommended, consider switch to LMWH
PLT < 25,000/ μ l	Discontinue temporarily	Not recommended	Not recommended
Kidney failure			
GFR 30–50 mL/min	Therapeutic dose	Therapeutic dose [§] (INR target range 2.0–3.0)	A, R therapeutic dose D, E consider dose reduction
GFR 15-<30 mL/min	50% of therapeutic dose ⁺		A, E, R use with caution and consider dose reduction D not recommended
GFR <15 mL/min	Not recommended		Not recommended
Liver cirrhosis			
Child-Pugh A	Therapeutic dose	Therapeutic dose [#] (INR target range 2.0–3.0)	Therapeutic dose
Child-Pugh B			A, D, E therapeutic dose ^{###} R not recommended
Child-Pugh C			Not recommended

Notes: *In several countries the DOACs are currently not licensed for the treatment of SVT patients. **Limited experience is available in patients with platelet count <100,000/ μ L, consider switching to LMWH or VKA. ***In patients with acute thrombosis and high risk of thrombus progression, consider therapeutic LMWH dose and platelet transfusion support to maintain a platelet count of \geq 40–50,000/ μ L. ⁺Consider monitoring the anti-factor Xa activity (target range 0.6–1.0 U/mL for enoxaparin BID, >1.0 U/mL for enoxaparin OD) or switching to UFH. Enoxaparin is the most studied LMWH in patients with kidney failure. [§]Patients with chronic kidney disease (low GFR values) might require lower doses to maintain the INR within the therapeutic range. [#]Since INR might not reflect the anticoagulation status, caution should be used in patients with Child-Pugh C class. ^{###}use with caution if liver enzymes > 2 ULN.

Abbreviations: A, apixaban; BID, twice daily; D, dabigatran; DOAC, direct oral anticoagulant; E, edoxaban; GFR, glomerular filtration rate; INR, international normalized ratio; LMWH, low molecular weight heparin; OD, once daily; PLT, platelet count; R, rivaroxaban; UFH, unfractionated heparin; ULN, upper limit of normal; VKA, vitamin K antagonist.

according to a stepwise approach with angioplasty/stenting or thrombolysis, followed by trans-jugular intrahepatic portosystemic shunting (TIPS) and, at last, orthotopic liver transplantation.^{2,3} It has been reported that approximately half of BCS patients require interventional procedures.⁹⁹

Prognosis

Data from several observational studies showed that the prognosis of SVT depends on several variables, such as older age, underlying risk factors (e.g. active cancer and MPN), site and extension of SVT.^{16,21} In an international prospective cohort study evaluating the long-term clinical outcomes of 604 patients with SVT, the mortality rate was 10.3 per 100 patient-years (95% CI, 8.5 to 12.5) during a median follow-up of 2 years.¹⁹ The highest and the lowest mortality rates

were reported, respectively, in patients with solid cancer (39.5 per 100 patient-years; 95% CI, 31.1 to 50.1) and with unprovoked SVT (2.3 per 100 patient-years; 95% CI, 1.1 to 4.8).¹⁹ Data from Danish registries showed that MVT was associated with the highest 30-day mortality rate (63.1%), followed by PVT and BCS (15.6% and 13.2%, respectively).¹⁸

Furthermore, SVT carry also an increased risk of bleeding events and arterial cardiovascular events.¹⁰⁰ The risk of bleeding was particularly relevant in the first 30 days (4.3% in SVT patients vs 0.5% in patients with DVT or PE), and remained significantly higher than usual site VTE up to 10 years after SVT diagnosis. The risk of cardiovascular events was also particularly relevant in the first 30 days (3.3% in SVT patients vs 0.9% in patients with DVT or PE), but remained high up to 1 year.¹⁰⁰

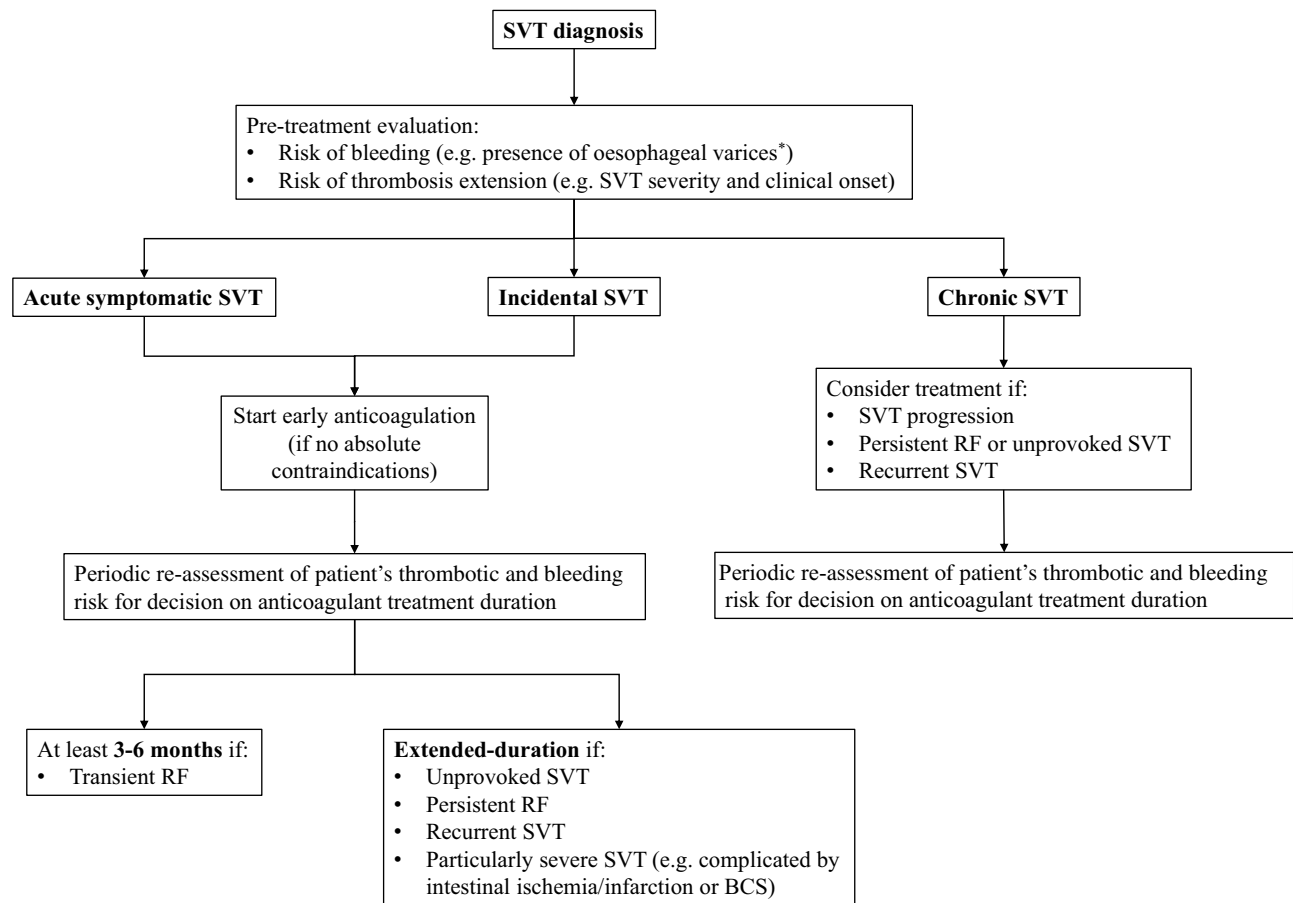

Figure 1 Suggested algorithm for the treatment of splanchnic vein thrombosis. *Consider prophylaxis of oesophageal bleeding (if varices).

Abbreviations: BCS, Budd-Chiari syndrome, RF, risk factor, SVT, splanchnic vein thrombosis.

Conclusions

SVT represents a diagnostic and therapeutic challenge. Based on limited available evidence, treatment decisions should be individualized with careful evaluation of the risks of bleeding and SVT recurrence or extension. The presence of oesophageal varices does not represent an absolute contraindication for anticoagulant therapy, but medical and endoscopic prophylaxis are warranted before starting anticoagulation to reduce bleeding risk. LMWH and VKA are the treatment of choice for SVT whereas the use of DOACs remains still off-label in several countries. Recent evidence suggests that incidentally detected SVT has similar prognosis as symptomatic SVT and a similar treatment approach is suggested. Treatment of chronic SVT is still controversial, especially in cirrhotic patients, but it should be considered in patients with persistent risk factors or selected cases at high risk of progression. Similarly to usual site VTE, a short course of anticoagulation (up to 6 months) is suggested for SVT provoked by transient risk factors, whereas longer treatment duration should be considered for

unprovoked SVT, SVT provoked by persistent risk factors, and SVT with a high risk of recurrence or progression.

A great scientific effort has been made in the past years trying to clarify some of the challenges associated with SVT. However, future studies will be needed to strengthen some areas of uncertainty including both the diagnostic (e.g. identification of new underlying diagnostic and prognostic risk factors) and therapeutic approaches (e.g. identification of which patients to treat, which anticoagulant to use and the duration of treatment) to SVT.

Disclosure

EV and NR report no conflicts of interest in relation to this paper. MDN reports personal fees from Bayer, Daiichi Sankyo, Pfizer, Leo Pharma, and Aspen, outside the submitted work. WA has received a research grant from Bayer to support a clinical study in patients with splanchnic vein thrombosis, received honoraria for participation at advisory boards from Bayer, Boehringer Ingelheim, Daiichi Sankyo, BMS/Pfizer, Sanofi, and Portola, and reports

grants and personal fees from Bayer, and personal fees from BMS/Pfizer, Daiichi Sankyo, Sanofi, Aspen, and Portola, outside the submitted work. The authors report no other conflicts of interest in this work.

Vascular Health and Risk Management

Dovepress

Publish your work in this journal

Vascular Health and Risk Management is an international, peer-reviewed journal of therapeutics and risk management, focusing on concise rapid reporting of clinical studies on the processes involved in the maintenance of vascular health; the monitoring, prevention and treatment of vascular disease and its sequelae; and the involvement

of metabolic disorders, particularly diabetes. This journal is indexed on PubMed Central and MedLine. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
