Purpose: A new carboxymethylcellulose (CMC)-containing ophthalmic formulation of 0.45% ketorolac, pH 6.8 (Acuvail®) was recently developed for treatment of inflammation and pain after cataract surgery. This study compared pharmacokinetics of the new formulation with that of a prior formulation, 0.4% ketorolac, pH 7.4 (Acular LS®).

Methods: Ketorolac formulations were administered bilaterally (35 µL) to female New Zealand White rabbits. Samples from aqueous humor and iris-ciliary body were collected at multiple time points, and ketorolac was quantified using liquid chromatography-tandem mass spectrometry.

Results: In aqueous humor, the peak concentration (C_{max}) and area under the concentration-time curve (AUC_{0-t}) of ketorolac were, respectively, 389 ng/mL and 939 ng·h/mL following administration of the CMC-containing 0.45% ketorolac, pH 6.8, and 211 ng/mL and 465 ng·hr/mL following administration of the 0.4% ketorolac, pH 7.4. In iris-ciliary body, C_{max} and AUC_{0-t} of ketorolac were, respectively 450 ng/g and 2040 ng·h/g after administration of the CMC-containing 0.45% ketorolac, pH 6.8, and 216 ng/g and 699 ng·h/g after administration of the 0.4% ketorolac, pH 7.4. PK simulations predicted an $AUC_{0-\tau}$ of 2910 ng·h/g for twice daily, CMC-containing 0.45% ketorolac, pH 6.8, compared to 725 ng·h/g for 4 times daily, 0.4% ketorolac, pH 7.4.

Conclusions: The CMC-containing formulation of 0.45% ketorolac, pH 6.8, increased ketorolac bioavailability by 2-fold in aqueous humor and by 3-fold in iris-ciliary body in comparison to the 0.4% ketorolac, pH 7.4, allowing a reduced dosing schedule from 4 times daily to twice daily.

Keywords: Acuvail, Acular LS, inflammation, ketorolac, ocular pharmacokinetics, twice-daily dosing

Introduction

Ketorolac is a nonsteroidal anti-inflammatory drug with analgesic and anti-inflammatory properties.¹ Currently available ophthalmic formulations of ketorolac include a 0.5% solution (Acular®; Allergan Inc., Irvine, CA), indicated for treatments of inflammation following cataract extraction and ocular itching due to seasonal allergic conjunctivitis, and a 0.4% solution, (Acular LS®; Allergan Inc.), indicated for treatment of pain and burning/stinging after corneal refractive surgery.^{2,3} Both of these ketorolac formulations are indicated for instillation 4 times daily.

Several clinical studies have demonstrated the safety and efficacy of the 0.5% and 0.4% ketorolac formulations for the alleviation of ocular inflammation and pain, prevention and treatment of cystoid macular edema, and/or prevention of

intraoperative miosis in ocular surgery patients.⁴⁻¹⁰ With 20% less active ingredient, the 0.4% ketorolac was demonstrated to be equivalent in potency to the 0.5% ketorolac in animal and human studies.^{8,11} Both the 0.4% and 0.5% ketorolac solutions, however, contain the preservative benzalkonium chloride (BAK), the surfactant octoxynol-40, and the metal-chelating agent sodium edetate and are associated with a high incidence of burning and stinging upon instillation.^{2,3,9}

The formulation of ophthalmic solutions can profoundly affect the safety, bioavailability, and tissue distribution of the active ingredients. To enhance the ocular bioavailability and tolerability of ketorolac, various modifications were made to the 0.4% ketorolac formulation, which included increasing the concentration of active ingredient, lowering formulation pH, adding carboxymethylcellulose (CMC), and excluding preservative, surfactant, and metal chelating agents. The purpose of this study was to evaluate the impact of these modifications on the ocular pharmacokinetics (PK) of ketorolac.

Methods

Ketorolac formulations

The ophthalmic solution of 0.4% ketorolac (Acular LS) contains 0.006% BAK, sodium chloride, 0.015% edetate disodium, octoxynol-40, purified water, and hydrochloric acid and/or sodium hydroxide to adjust the pH to approximately 7.4.² For the formulations tested here: a) the preservative BAK, the metal-chelating agent edetate disodium, and the surfactant octoxynol-40 were omitted; b) CMC was added as a viscosity agent; and c) the concentration of ketorolac was increased to 0.45%. The pH was adjusted by the addition of hydrochloric acid or sodium hydroxide.

PK sampling

A 35 μ L aliquot of test formulations or 0.4% ketorolac was topically administered to each eye of female New Zealand White rabbits (Covance Research Products Inc., Denver, PA). Samples from aqueous humor ($n = 6$ eyes of 3 rabbits/timepoint) were collected at 1, 2, and 4 hours postdose. Samples from iris-ciliary body ($n = 4$ eyes of 2 rabbits/timepoint) were collected at 1, 2, 4, and 8 hours postdose. Animals were euthanized with an intravenous injection of sodium pentobarbital. All protocols were reviewed and approved by the Institutional Animal Care and Use Committee, and the study conformed to the principles of animal use set forth by the Association for Research in

Vision and Ophthalmology Statement for Use of Animals in Ophthalmic and Vision Research.

Ketorolac extraction and quantification

Ketorolac concentrations in aqueous humor and iris-ciliary body were determined after liquid-liquid extraction by a liquid chromatography-tandem mass spectrometry (LC-MS/MS). Iris-ciliary body samples were prepared for extraction by homogenization in 1 mL of 50% methanol. Finasteride (500 ng/mL; 10 μ L) was then added to 50 μ L aliquots of aqueous humor and to 300 μ L aliquots of the homogenized iris-ciliary body samples. Since stable-isotope labeled ketorolac is not available, finasteride, which has an approximately similar retention time on liquid chromatography, was used as an internal standard. Ketorolac was extracted with methyl tert-butyl ether. The organic extracts were evaporated to dryness, and the precipitates were reconstituted with 40% acetonitrile for injection onto the LC-MS/MS system utilizing an atmospheric-pressure chemical ionization heated nebulizer source. Ketorolac quantification was conducted in the positive ion multiple reaction-monitoring mode.

Data analysis

Thermo Electron WatsonTM (Thermo Electron Corporation, Waltham, MA) software was used for PK calculations. All samples were analyzed for peak concentrations (C_{max}), time to C_{max} (T_{max}), and area under the concentration-time curve from time 0 to the sampling time (AUC_{0-t}) using the random method for nonsequential sampling. Relative bioavailability (relative %F) was expressed as the percentage of the AUC_{0-t} of the 0.4% ketorolac following a single ocular instillation (35 μ L). PK simulations were performed using WinNonlin Enterprise (Pharsight, Mountain View, CA).

Statistical analysis

Between-group differences in iris-ciliary body C_{max} were evaluated by one-way analysis of variance (ANOVA) and Dunnett's multiple comparison test. $P < 0.05$ was considered a statistically significant difference.

Results

Effects of CMC and pH on ketorolac PK in aqueous humor

The PK of the CMC-containing test formulations at different pH were compared to that of the 0.4% ketorolac (Acular LS) (Table 1). At pH = 7.4, the inclusion of CMC

Table 1 Aqueous Humor pharmacokinetics of ketorolac following administration of the 0.4% ketorolac, pH 7.4 (Acular LS), and the CMC-containing 0.45% ketorolac, pH 6.8 (Acuvail), formulations at varying pH

Ketorolac (%w/v)	CMC	pH	T _{max} (hour)	C _{max} (ng/mL [SD])	AUC ₀₋₄ (ng·h/mL [SEM])	Relative %F
0.40	–	7.4	1.0	211 (106)	465 (65)	100
0.45	+	7.4	2.0	265 (71)	627 (51)	135
0.45	+	7.2	1.0	240 (84)	619 (50)	133
0.45	+	7.0	1.0	268 (125)	658 (73)	142
0.45	+	6.8	2.0	389 (258)	939 (163)	202

Abbreviations: AUC₀₋₄, area under the concentration-time curve from time 0 to 4 hours; CMC, carboxymethylcellulose; C_{max}, peak concentration; relative %F, percentage of the AUC₀₋₄ value compared to that of the 0.4% ketorolac; SEM, standard error of the mean; SD, standard deviation; T_{max}, time to C_{max}.

as well as a 12.5% increase in ketorolac concentration enhanced ketorolac bioavailability in aqueous humor by 35% compared to ketorolac 0.4% (AUC₀₋₄ [SEM] of 627 ± 51 ng·h/mL versus 465 ± 65 ng·h/mL, respectively). Decreasing the pH from 7.4 to 6.8 in combination with the addition of CMC enhanced ketorolac bioavailability in aqueous humor by 2-fold compared to ketorolac exposure following the 0.4% ketorolac administration (AUC₀₋₄ [SEM] of 939 ± 163 ng·h/mL versus 465 ± 65 ng·h/mL, respectively) (Table 1). Temporal kinetics of aqueous ketorolac concentrations following instillation of the CMC-containing 0.45% ketorolac, pH 6.8, or the 0.4% ketorolac, pH 7.4, are presented in Figure 1a.

Effects of CMC and pH on ketorolac PK in iris-ciliary body

In iris-ciliary body, the C_{max} (SD) and AUC₀₋₈ (SEM) of ketorolac were, respectively, 450 ± 117 ng/g and 2040 ± 240 ng·h/g following administration of the CMC-containing 0.45% ketorolac, pH 6.8, and 216 ± 43 ng/g and 699 ± 74 ng·h/g after administration of the 0.4% ketorolac (Table 2). The between-group difference in ketorolac C_{max} was statistically significant ($P < 0.05$). Overall, ketorolac bioavailability increased by 3-fold in iris ciliary body following administration of the CMC-containing 0.45% ketorolac, pH 6.8, compared to the 0.4% ketorolac, pH 7.4. Temporal kinetics of ketorolac concentrations in iris-ciliary body following instillation of the CMC-containing 0.45% ketorolac, pH 6.8, or the 0.4% ketorolac, pH 7.4, are presented in Figure 1b.

PK simulation of ketorolac concentrations following multiple dose administration over a 24-hour period

PK simulations of multiple-dose regimens derived from data collected following a single dose predicted an AUC_{0-τ} of 2910 ng·h/g for twice daily, CMC-containing 0.45%

ketorolac, pH 6.8, compared to 725 ng·h/g for 4 times daily 0.4% ketorolac, pH 7.4 (Figure 2).

Discussion

Ketorolac ophthalmic formulations have been used successfully since 1997 for the control of inflammation after cataract surgery and the reduction of pain after refractive surgery. However, both the 0.4% ketorolac solution (Acular LS) and

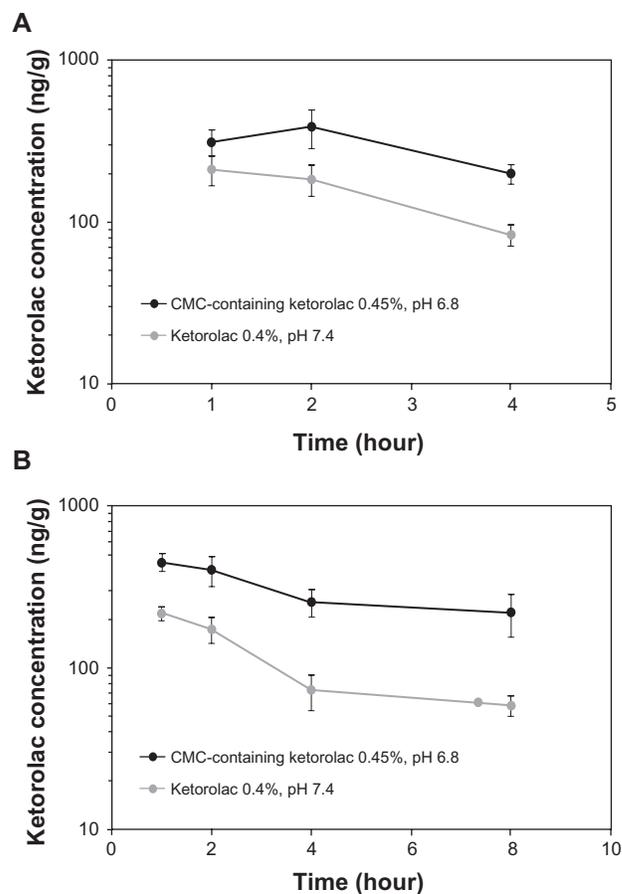

Figure 1 Temporal kinetics of ketorolac concentrations (±SEM) following a single topical administration of the CMC-containing 0.45% ketorolac, pH 6.8 (Acuvail), and the 0.4% ketorolac, pH 7.4 (Acular LS), in aqueous humor (a) and iris-ciliary body (b). **Abbreviation:** CMC, carboxymethylcellulose.

Table 2 Pharmacokinetics of ketorolac in iris-ciliary body following administrations of the CMC-containing 0.45% ketorolac, pH 6.8 (Acuvail), and the 0.4% ketorolac, pH 7.4 (Acular LS)

	T _{max} (hour)	C _{max} (ng/g [SD])	AUC ₀₋₄ (ng·h/g [SEM])	Relative %F
CMC-containing 0.45% ketorolac, pH 6.8	1.0	450 ^a (117)	2040 (240)	292
0.4% ketorolac, pH 7.4	1.0	216 (43)	699 (74)	100

Note: ^aP < 0.05 compared to the 0.4% ketorolac, pH 7.4 (Acular LS).

Abbreviations: AUC₀₋₄, area under the concentration-time curve from time 0 to 4 hours; CMC, carboxymethylcellulose; C_{max}, peak concentration; relative %F, percentage of the AUC₀₋₄ value compared to that of the 0.4% ketorolac; SEM, standard error of the mean; SD, standard deviation; T_{max}, time to C_{max}.

the 0.5% ketorolac solution (Acular) were associated with a high incidence of burning and stinging upon instillation as reported in their package inserts (“20%–40%” and “up to 40%”, respectively).^{2,3} The high rate of burning and stinging may negatively impact patient acceptance and compliance.

The most important finding of the current study was that the CMC-containing 0.45% ketorolac, pH 6.8 (Acuvail®; Allergan Inc., Irvine, CA), delivered higher ketorolac concentrations to aqueous humor and iris-ciliary body than did the 0.4% ketorolac, pH 7.4. The new formulation also provided greater aqueous humor exposure to ketorolac in comparison to historical PK data from the 0.5% ketorolac formulation, pH 7.4 (AUC₀₋₄ = 939 ng·h/mL versus AUC₀₋₄ = 583 ng·h/mL, respectively).¹² The 0.5% ketorolac formulation, pH 7.4, achieves <4% absolute ocular bioavailability in the anterior chamber.¹²

Low ocular bioavailability following topical administration is a well recognized challenge in ophthalmic drug delivery, which is attributed to the drainage of the majority of drug through the nasolacrimal duct. In comparison to the anterior chamber, it is even more difficult for topical NSAIDs to penetrate into and maintain therapeutic levels

in the posterior chamber. Previous studies demonstrated that the 0.4% ketorolac penetrated into vitreous and significantly lowered vitreous prostaglandin E₂ levels compared to control.¹³ Further studies are warranted to evaluate whether the new 0.45% formulation can deliver higher concentrations of ketorolac into the posterior chamber compared to the 0.4% ketorolac.

In this study, factors that contributed to the improvement of ketorolac delivery into ocular tissues were a small increase in ketorolac concentration, the addition of CMC, and a decrease in formulation pH. CMC is a cellulose derivative that is soluble in aqueous solutions and is used to provide viscosity without gelling. CMC increases the ocular residence time of topical ophthalmic drugs and thereby enhances ocular absorption.^{14–16} In our study, the addition of CMC to a formulation of 0.45% ketorolac at pH = 7.4 substantially increased ketorolac absorption into aqueous humor in comparison to the CMC-free 0.4% ketorolac, pH 7.4. An additional benefit of the use of CMC in ophthalmic solutions is its ability to promote corneal epithelial wound healing.¹⁷ This feature is important for ophthalmic treatments following cataract surgery.

The un-ionized form of a drug is more readily available for ocular absorption than the ionized form. The primary factor affecting ionization is pH.¹⁸ With a pK_a of 3.5, ketorolac is mostly ionized in the pH range of 6.8 to 7.4, according to the Henderson–Hasselbalch equation, $pH = pK_a + \log[A^-]/[HA]$, where [A⁻] and [HA] represent the concentration of ionized and un-ionized ketorolac, respectively.¹⁸ As the pH is decreased from 7.4 to 6.8, relatively more ketorolac becomes un-ionized and, as a corollary, bioavailable. For the CMC-containing 0.45% ketorolac formulation, a shift from pH 7.4 to pH 6.8 results in 4-fold higher percentage of un-ionized drug that is available for absorption (0.0125% versus 0.05%, respectively).

Other formulation modifications included the omission of BAK, edetate disodium, and octoxynol-40. BAK has been shown to promote absorption of some ophthalmic drugs.¹⁹ The impact of BAK on ocular absorption of ketorolac is, however, controversial. In vivo, BAK did not improve the

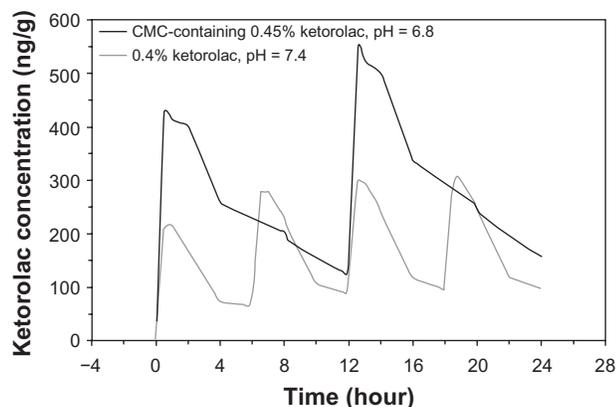

Figure 2 Simulation of ketorolac concentrations in iris-ciliary body following multiple topical administrations of the CMC-containing 0.45% ketorolac, pH 6.8 (Acuvail), and the 0.4% ketorolac, pH 7.4 (Acular LS).

Abbreviation: CMC, carboxymethylcellulose.

bioavailability of ketorolac in rabbits with intact corneas and decreased ocular absorption of ketorolac in rabbits with de-epithelialized corneas.²⁰ In vitro, however, BAK improved the rate of ocular absorption of ketorolac.²¹ Nevertheless, reformulation of ketorolac without BAK, edetate disodium, and octoxynol-40 may improve tolerability and ocular comfort.

With a longer retention time and higher bioavailability on the ocular surface, the CMC-containing 0.45% ketorolac, pH 6.8, exhibits the potential for use at longer intervals. PK simulations indicated that twice daily instillation of the new formulation may provide greater drug exposure than does 4 times daily instillation of 0.4% ketorolac, pH 7.4, in iris-ciliary body over a 24-hour period. Considering the omission of the preservative, surfactant, and metal-chelating agents, this finding suggests that the CMC-containing 0.45% ketorolac, pH 6.8, is likely to provide a similar efficacy to those of the 0.4% and 0.5% formulations in reducing inflammation and pain but with improved ocular comfort at a reduced dosing frequency. Pivotal phase 3 trials have recently demonstrated that twice daily instillation of the CMC-containing 0.45% ketorolac, pH 6.8, was well tolerated and effectively treated both inflammation and pain in cataract surgery patients.²² Based on these findings, the Food and Drug Administration approved twice-daily CMC-containing 0.45% ketorolac for treatment of ocular inflammation and pain following cataract surgery.²³ In addition to convenience, a less frequent dosing regimen may increase patient compliance and adherence to the recommended dosing schedule.^{24,25} Together these data demonstrate that by targeting formulation modifications to the small fraction of drug available for absorption, substantial effects on increasing ocular penetration can be observed. Further studies are warranted to compare the PK and efficacy of the new ketorolac formulation to those of other ophthalmic NSAIDs for the treatment of prostaglandin-mediated ocular inflammatory conditions.
