**Background:** Tumor angiogenesis plays a crucial role in tumor development, and recent efforts have been focused on combining proapoptotic and antiangiogenic activities to enhance antitumor therapy.

**Methods:** In this study, galactose-modified liposomes (Gal-LPs) were prepared for co-delivery of doxorubicin (DOX) and combretastatin A4 phosphate (CA4P). The co-cultured system composed of BEL-7402 and human umbilical vein endothelial cells (HUVEC) cells was established to effectively evaluate in vitro anti-tumor activity through cell viability and cell migration assay. Furthermore, both in vivo bio-distribution and anti-hepatoma effect of DOX&CA4P/Gal-LPs were investigated on H22 tumor cell-bearing mice.

**Results:** The results showed that DOX&CA4P/Gal-LPs were spherical with a mean particle size of 143 nm, and could readily be taken up by BEL-7402 cells. Compared with a mixture of free DOX and CA4P, the DOX&CA4P/Gal-LPs were more effective in inhibiting cell migration and exhibited stronger cytotoxicity against BEL-7402 cells alone or a co-cultured system. The in vitro studies showed that the co-cultured system was a more effective model to evaluate the anti-tumor activity of combination therapy. Moreover, DOX&CA4P/Gal-LPs exhibited a greater anti-hepatoma effect than other drug formulations, indicating that Gal-LPs could promote drug accumulation in the tumor region and improve the anti-tumor activity.

**Conclusion:** Gal-LPs co-loaded with chemotherapeutic and antiangiogenic drugs are a promising strategy for anti-hepatoma therapy.

**Keywords:** liposomes, anti-hepatoma, co-delivery, combination therapy

## Introduction

More and more evidence has been provided that traditional therapy based on a single anti-tumor drug fails to eliminate the tumor due to the complexity of tumor development.<sup>1</sup> Accordingly, combination therapy has been widely applied as an effective strategy by combining two or more drugs via different antitumor mechanisms.<sup>2,3</sup> Nowadays, it has attracted great attention in the combination of chemotherapeutic and anti-angiogenic agents for an enhanced anti-tumor effect.<sup>4,5</sup> In this strategy, the anti-angiogenic drugs could induce the blood vessel shutdown by targeting the abnormal vasculature, while the chemotherapeutic drugs could inhibit tumor development by pro-apoptotic activities, herein leading to a superior antitumor effect.<sup>6-8</sup>

The tumor angiogenesis plays an important role in the process of tumor development and metastasis. Anti-angiogenesis therapy has emerged as a potential strategy in the inhibition of tumor growth by blocking the nutrient supply.<sup>9,10</sup> Recent research has been

focused on the development of new anti-angiogenic agents.<sup>11,12</sup> Among these, combretastatin-A4 (CA4), a compound from *Combretum caffrum*, is a promising anti-angiogenic drug, which could induce vasoconstriction and collapse of blood vessels by targeting the abnormal vascular system.<sup>13–15</sup> Therefore, combining CA4 and chemotherapeutic drug, such as doxorubicin (DOX), is expected to inhibit tumor development by pro-apoptotic and anti-angiogenic activities simultaneously.

However, traditional combinational therapy by a mixture of free drugs has exhibited many disadvantages in clinics, such as systemic toxicity, lack of selectivity, and low bio-availability.<sup>16,17</sup> In order to improve the selectivity and reduce the systemic side-effects, it is necessary to prepare an efficient co-loaded drug delivery system, which could carry two or more drugs into the tumor region, and effectively be taken up by tumor cells.<sup>13,18</sup> In the past few decades, liposomes (LPs) modified by special moieties, such as antibodies, sugars, and various ligands, have been utilized for targeting delivery of anti-tumor drugs.<sup>19–21</sup> Compared with normal liver tissue, the asialoglycoprotein-receptor (ASGP-R) is over-expressed on the surface of tumor cells in Hepatocellular Carcinoma (HCC).<sup>22,23</sup> The liposomes modified by galactose (Gal),

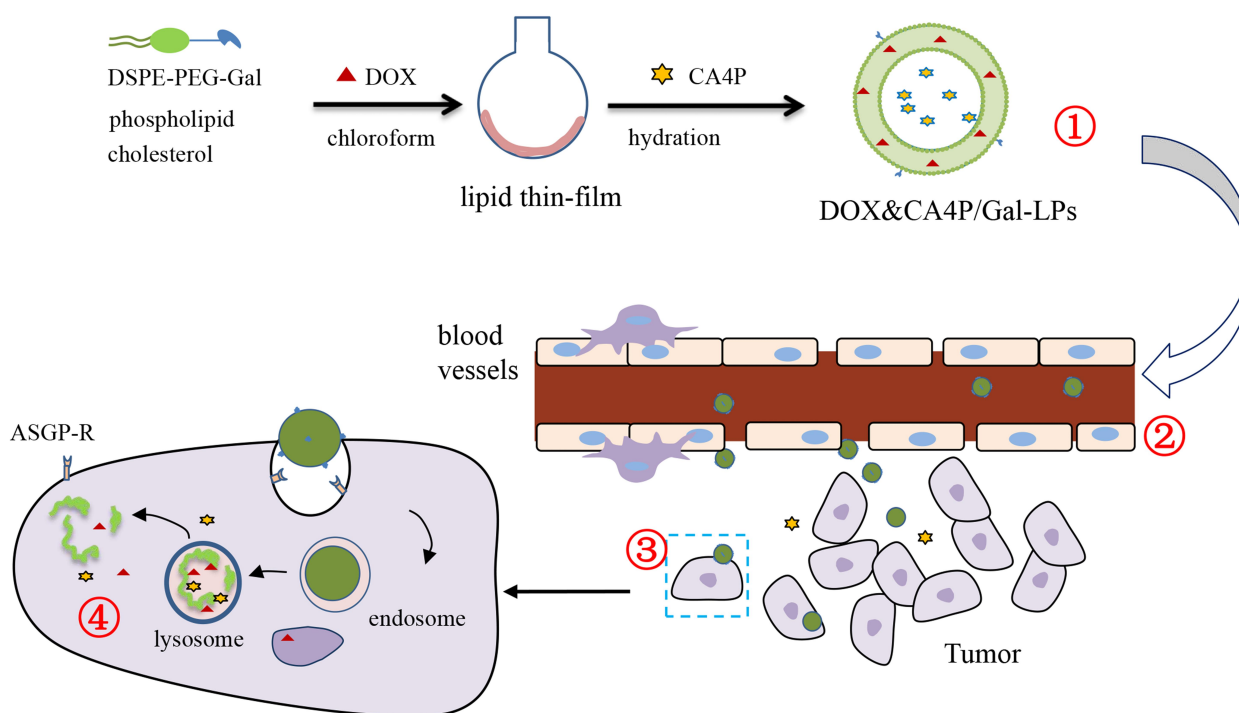

a molecular specially binding to ASGP-R, were expected to improve the efficacy of combination therapy.

In this study, Gal-modified liposomes were prepared for co-delivery of DOX and CA4P to inhibit HCC development through pro-apoptotic and anti-angiogenic activities (Figure 1). A co-cultured system composed of BEL-7402 and HUVEC cells was established to investigate the combination therapeutic effects in vitro. The in vivo real-time near-infrared fluorescence (NIRF) imaging was performed to explore the targeting properties of Gal-LPs, and H22 tumor-bearing mice were used to evaluate the anti-hepatoma efficacy of DOX&CA4P co-loaded liposomes in vivo.

## Materials and Methods

### Materials

CA4P (MW: 440.30), Lactobionic acid (LA, MW: 358.3) and cholesterol were purchased from Beijing Innochem Co., Ltd. (China). L- $\alpha$ -phosphatidylcholine, Thiazolyl blue tetrazolium bromide (MTT, MW:414.3), fetal bovine serum (FBS) and 4',6-Diamidino-2-phenylindole (DAPI, MW:350.2) were obtained from Beijing Solarbio Co., Ltd. (China). DOX was obtained from Shanxi Powerdone Pharmaceutical Co., Ltd (China). DSPE-PEG-NHS was

**Figure 1** Schematic illustration of combination therapy. ①Preparation of DOX&CA4P/Gal-LPs, ②Liver-targeting delivery via blood cycle, ③Cellular uptake mediated by ASGP-R, and ④Drug release in tumor cells.

obtained from Xi'an Ruixi Technology Co., Ltd. (China). All other chemicals were of analytical grade.

## Cell Culture

Human hepatic cell line (BEL-7402), Hela, and HUVEC cells were obtained from Beijing Bnbio Research Institute (China). An in vitro co-cultured system was established by mixing BEL7402 and HUVEC cells in RPMI 1640 medium at a ratio of 5:1.

## Animals

Female BALB/c mice (age: 6~8 weeks; weight: approximately 18–20 g) were purchased from Jinan Pengyue Experimental Animal Breeding (China); All animal experiments were approved by the WFMU Animal Research Ethics Committee, approval No. 2019–045. Care and handling of the animals were in strict compliance with the “Guide for the Care and Use of Laboratory Animals” of China.

## Preparation and Characteristics of Co-Loaded Liposomes

DSPE-PEG-Gal was synthesized by a two-step reaction between DSPE-PEG-NHS and LA according to previous studies.<sup>24</sup> Gal-LPs were prepared by thin-film evaporation. Briefly, L- $\alpha$ -phosphatidylcholine, cholesterol, and DSPE-PEG-Gal were mixed in chloroform at a mass ratio of 12:4:1. The particle size,  $\zeta$  potential, and polydispersing index (PDI) of Gal-LPs were characterized using dynamic light scattering method with a wavelength of 633 nm at 25°C. The morphology of the blank LPs and Gal-LPs was observed by transmission electron microscopy (TEM, HT7700, HITACHI, Japan). Briefly, one drop of Gal-LPs solution was placed on a copper grid. After drying, the sample was stained with 2% phosphotungstic acid, and then observed under TEM.

DOX&CA4P/Gal-LPs were prepared for combination therapy. In brief, a mixed solution of L- $\alpha$ -phosphatidylcholine, cholesterol, and DOX in chloroform was evaporated to form a dry lipid film. The CA4P solution in PBS was added to hydrate the lipid film, followed by sonicating the mixture solution for smaller particle size. Meanwhile, DOX&CA4P/LPs were prepared for control. The characteristics of drug-loaded LPs were tested as before.<sup>25</sup> To evaluate the stability of DOX&CA4P/Gal-LPs, the samples were dispersed in serum-free RPMI 1640 medium. The particle size and  $\zeta$  potential were measured using

dynamic light scattering (Zetasizer Nano ZS90, Malvern, England) for 15 days. CA4P was measured using high-performance liquid chromatography (HPLC, Agilent1260, USA). The mobile phase was composed of 60% of methanol and 40% of 0.05 M KH<sub>2</sub>PO<sub>4</sub> solution, and flow rate was fixed at 1 mL/min. In total, 20  $\mu$ L of sample was injected and the total run time was 8 minutes. DOX was detected at 490 nm using a UV/VIS spectrophotometer (UV-8000, Shanghai, China). The encapsulation efficiency (EE) and loading efficacy (DL) were measured using high-performance liquid chromatography (HPLC), and calculated according to the following formulae:  $EE = W_s/W_a \times 100\%$ , where  $W_s$  stands for the amounts of DOX or CA4P loaded in the LPs, while  $W_a$  means the initial added amounts of DOX or CA4P added. These studies were repeated in triplicate.

## In vitro Drug Release from LPs

The release profiles of DOX and CA4P from LPs were investigated by dialysis method. DOX&CA4P/Gal-LPs were dispersed in PBS (pH 7.4), and the solution was transferred into a dialysis bag (MWCO of 3.5 kDa). Then, the dialysis bag was placed in a bottle containing 20 mL of release medium (PBS buffer solution containing 0.5% Tween 80). The release system is kept in a shaking incubator under a shaking speed of 100 rpm at 37°C. At predetermined time intervals (0.5, 1, 2, 4, 8, 12, 24, and 48 hours), 2 mL of medium was taken out and the same amounts of free release solution were added. The concentrations of DOX and CA4P were measured based on their standard curve, respectively, and their cumulative release percentages ( $Er$ ) were calculated by the following equation:

$$Er(\%) = \frac{V_r \sum_{i=1}^{n-1} C_i + V_o C_n}{M_d} \times 100\%$$

Where  $M_d$  is the amount of DOX or CA4P in the LPs,  $V_o$  stands for the whole volume of release medium,  $C_i$  is the concentration of drugs in release medium, and  $V_r$  stands for the volume of the replaced medium.

## In vitro Cellular Uptake

In vitro cellular uptake was performed to evaluate the active-targeting properties of Gal-LPs.<sup>26</sup> In brief, BEL-7402 or Hela cells were seeded in 6-well plates at a density of  $5 \times 10^4$  cells/mL at 37°C. After 18–24 hours of incubation, the media were replaced with 2 mL of fresh RPMI-1640 medium containing DOX&CA4P/LPs or DOX&CA4P/Gal-LPs (at the equivalent DOX concentration of 5  $\mu$ g/mL) for 4 hours of incubation, respectively.

Afterwards, the media were discarded, and the cells were washed with cold PBS. Furthermore, the cells were dyed by DAPI for 10 minutes and washed by PBS. Finally, the cellular uptake of drug-loaded LPs was visualized under a confocal microscope (TCS SP8, Leica, Germany) with the excitation wavelength at 361 nm for DAPI and 485 nm for DOX.

### In vitro Cytotoxicity Analysis

To evaluate the cytotoxicity of drug-loaded LPs, the MTT assay was performed against BEL-7402 cells alone or BEL7402/HUVEC co-cultured system, respectively. BEL-7402 cells or co-cultured cells (the ratio of BEL7402 to HUVEC at 5:1) were seeded in 96-well plates at a density of 5,000 cells/well for 18–24 hours. Then the media were replaced with serum-free fresh media containing DOX, a mixture of DOX and CA4P, DOX&CA4P/LPs, and DOX&CA4P/Gal-LPs, respectively. The DOX concentrations were set to be 0.01, 0.1, 1, 2, and 5 µg/mL. After 48 hours of incubation, 10 µL of MTT solution (0.5 mg/mL) was added to each well, and the cells were incubated for another 4 hours. Then, the media were discarded, and 150 µL of DMSO was added. The fluorescence intensity at 570 nm was recorded using a micro plate reader (Bio-Rad 500, USA).

### In vitro Cell Migration Assays

A 2D wound healing assay was performed to evaluate the effects of different drug formulations on cellular mobility in the Bel-7402 cells alone or BEL7402/HUVEC co-cultured system, respectively. In order to distinguish different cells in a co-cultured system, the 5.6-carboxyfluorescein diacetate, succinimidyl ester (CFSE)-labeled HUVEC cells model was established.<sup>27</sup> BEL-7402 cells or co-cultured system were seeded in a 6-well plate at a density of  $5 \times 10^4$  cells per well. After forming a confluent monolayer, the cells were scraped by a p200 pipet tip to create an empty gap. The media were replaced by fresh media with different drug formulations. The cells were imaged at 0 and 24 hours using microscopy, and the degree of wound healing was calculated by the following equation:

wound healing rate = (wound area on 0 hour – wound area on n hours)/(wound area on 0 hour)  $\times$  100%, where n = 24 hours post-wounding.

### In vivo Biodistribution

To investigate the liver-targeting property of Gal-LPs, DiR/Gal-LPs were prepared to track the in vivo

biodistribution of drugs. Briefly, the H22 tumor-bearing mice were established through injecting H22 cells subcutaneously on the right flank of female BALB/c mice. When the tumor volume reached 200 mm<sup>3</sup>, these mice were randomly divided into two groups and injected intravenously via the tail vein with free DiR or DiR/Gal-LPs. The in vivo distribution of DiR was observed by IVIS<sup>®</sup> Kinetics Optical System (PerkinElmer, USA). The excitation and emission wavelength were set at 710 nm and 790 nm, respectively.

### In vivo Antitumor Efficacy

H22 cell-bearing BALB/c mice were established to investigate the anti-hepatoma efficacy of different drug formulations. In brief, 0.2 mL of H22 cells at a concentration of  $4 \times 10^6$  cells/mL was subcutaneously inoculated into the flanks of BALB/c mice. When the tumor volume reached 100 mm<sup>3</sup>, the mice were randomized into five groups: saline (control), free DOX, mixture of DOX and CA4P, DOX&CA4P/LPs, and DOX&CA4P/Gal-LPs. The mice were injected through the tail vein every 2 days, and the dosage of DOX was set at 5 mg/kg. The mice were weighed, and tumor size was measured every 2 days. The tumor volumes were calculated according to the following equation:

$$V = a \times b^2 / 2$$

where a and b represent the long axis and short axis, respectively. After 2 weeks of administration, mice were euthanized, and the tumors were harvested and weighed. Finally, the growth-rate of inhibition (GRI) was calculated by the following equation:

$$\text{GRI} = (1 - W_s / W_c) \times 100\%$$

where  $W_s$  is the tumor weight of the drug-treated group, and  $W_c$  is the tumor weight of the control group.

### Immunohistochemistry and Histological Staining

At the end of drug administration, the major organs were harvested for immunohistochemistry and histological staining. In brief, the tumors and organs were fixed with 4% PBS buffered paraformaldehyde, and embedded in paraffin. The paraffin-embedded samples were cut into slices at 4 µm thickness using an ultrathin slicer, and histopathological changes were investigated by hematoxylin and eosin (H&E) staining via an inverted microscope (IX51; Olympus, Tokyo, Japan). To evaluate the anti-angiogenic

effect of combination therapy, the microvascular density of CD31 was measured by immunohistochemistry assay.

## Statistical Analysis

All experimental data in this study were expressed as mean±standard deviation (SD, n=3). Statistical significances were determined through a Student's *t*-test, and  $P<0.05$  was considered as statistically significant.

## Results and Discussion

### Characterizations of Drug-Loaded Liposomes

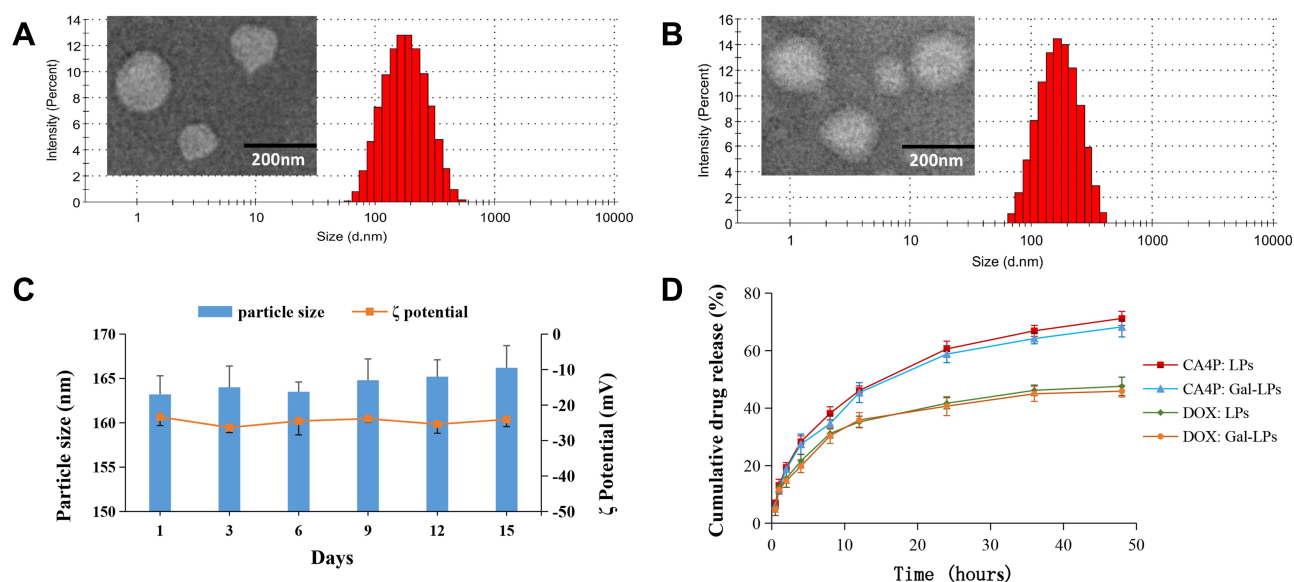

The results showed that DOX and CA4P could successfully encapsulate into Gal-LPs. The EE% values of DOX and CA4P were 86.74% and 52.43%, respectively. The DL% were 5.62% and 2.03%, respectively. The mean particle size and zeta-potential of DOX&CA4P/Gal-LPs were  $143.01 \pm 7.32$  nm and  $-24.18 \pm 3.45$  mV, respectively. And those of DOX&CA4P/LPs were  $137.12 \pm 4.59$  nm and  $-25.67 \pm 2.91$  mV, respectively. TEM images indicated that the shape of drug-loaded LPs was spherical (Figure 2A and B). Moreover, the stability of DOX&CA4P/Gal-LPs was determined in RPMI-1640 medium. There was no significant difference in the mean particle size and zeta-potential within 2 weeks, indicating that the liposomal formulation was stable under physiological conditions (Figure 2C).<sup>28</sup>

In vitro drug release from Gal-LPs was evaluated in the media at 37°C. Figure 2D shows that DOX and CA4P

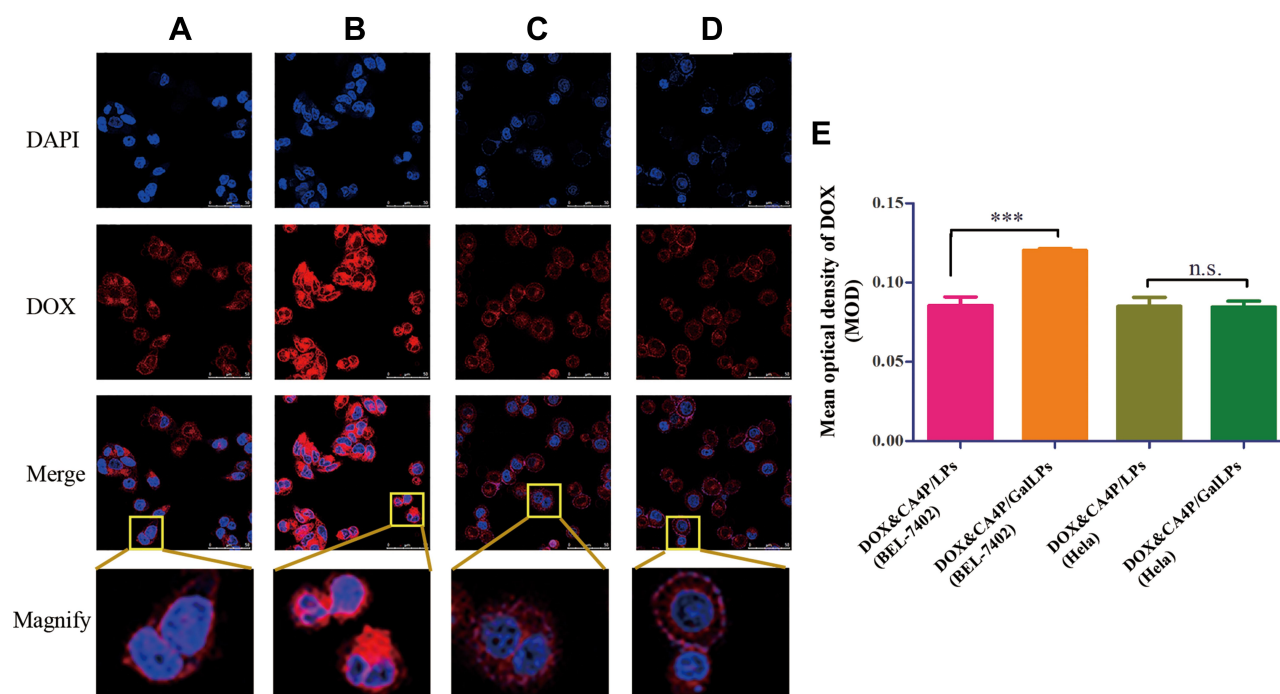

exhibited time-dependent release within 48 hours. Approximately 30% of CA4P and 20% of DOX was released from Gal-LPs at 4 hours, which was similar in the LPs. No obvious burst release was observed, indicating that nano-sized liposomes have sustained release properties.<sup>29</sup> At 48 hours, the cumulative drug releases from Gal-LPs were about 75% of CA4P and 45% of DOX, suggesting that, compared with hydrophobic DOX, CA4P has a higher release rate due to its hydrophobicity.

### In vitro Cellular Uptake

To analyze whether Gal-LPs is capable of active-targeting delivery of DOX into tumor cells, the cellular uptake of DOX was investigated in both BEL-7402 and Hela cells, respectively. The auto-fluorescence (Red) of DOX was used to track the distribution of DOX in cells, and the cell nuclei were dyed by DAPI (blue). As shown in Figure 3A and B, stronger fluorescence signals were observed in the cytoplasm and nuclei of BEL-7402 cells treated with DOX&CA4P/Gal-LPs in comparison with the DOX&CA4P/LPs, indicating that Gal-LPs could deliver more DOX into BEL-7402 cells than Gal-free liposomes. However, no obvious difference was observed in the Hela cells (Figure 3C–E). This was due to the different express level of ASGP-R between the BEL-7402 and Hela cells. ASGP-R was over-expressed on the cytomembrane of BEL-7402, therefore Gal-LPs could improve cellular uptake of DOX via ASGP-R-mediated endocytosis.<sup>30,31</sup> The results suggested that introduction of

Gal ligand on LPs could enhance the cell internalization of drug-loaded LPs, and Gal-LPs have the potential to carry anti-tumor drugs for anti-hepatoma therapy.

## Cytotoxicity Assay

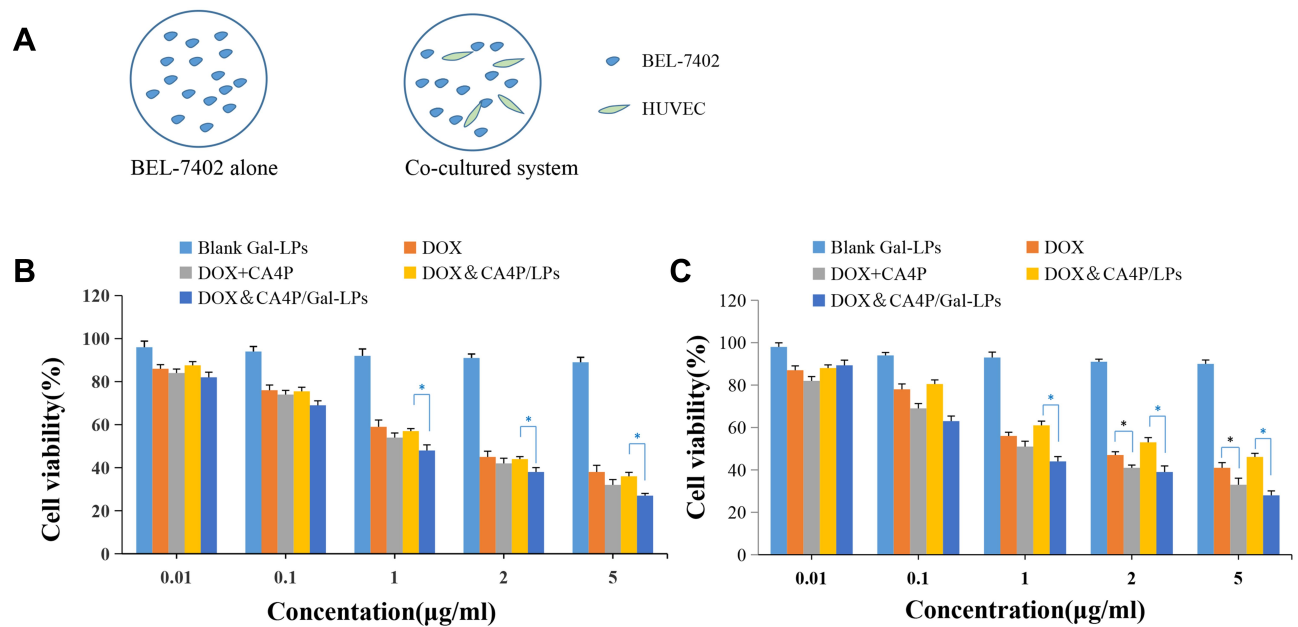

In this study, the combination therapy based on liposomes was designed by co-delivering two drugs with proapoptotic (DOX) and anti-angiogenic (CA4P) activities. However, It is difficult to exactly evaluate the anti-tumor effect by tumor cells alone *in vitro* due to different anti-tumor mechanisms of two drugs.<sup>32</sup> In order to mimic the interaction between tumor cells and vascular endothelial cells in the tumor environment, we established a co-cultured system which was composed of Bel-7402 and HUVEC cells to evaluate the anti-proliferation and anti-angiogenesis effects of the combination treatment.

To evaluate the cytotoxicity of different drug formulations, cellular viability against BEL-7402 cells or BEL-7402/HUVEC co-cultured system was investigated by MTT assay (Figure 4A). As shown in Figure 4B, the cellular viability of blank liposomes and Gal-LPs was over 85% at all concentrations (10–500 mg/mL), indicating that Gal-LPs had good bio-compatibility and were suitable to be used as the nanocarriers for anti-tumor drugs.<sup>32</sup> After 48 hours of incubation, free DOX, mixture of DOX and CA4P,

DOX&CA4P/LPs, and DOX&CA4P/Gal-LPs showed dose-dependent cytotoxicity against BEL7402 cells alone or a co-cultured system. Compared with treatment of free DOX, the combined formulations against co-cultured systems showed higher cytotoxicity, indicating that the combination of chemotherapeutic and antiangiogenic drugs exhibited stronger cytotoxicity than a single drug (Figure 4C). Moreover, similar to the BEL-7402 cells alone, the cellular viability of DOX&CA4P/Gal-LPs was lower than that of DOX&CA4P/LPs in the co-cultured system. The results suggested that introduction of Gal molecules on the surface of liposomes could increase the accumulation of DOX in cells, and thus lead to enhanced cytotoxicity, which was consistent with the analysis of cellular uptake.<sup>33,34</sup>

## In vitro Cell-Migration Assays

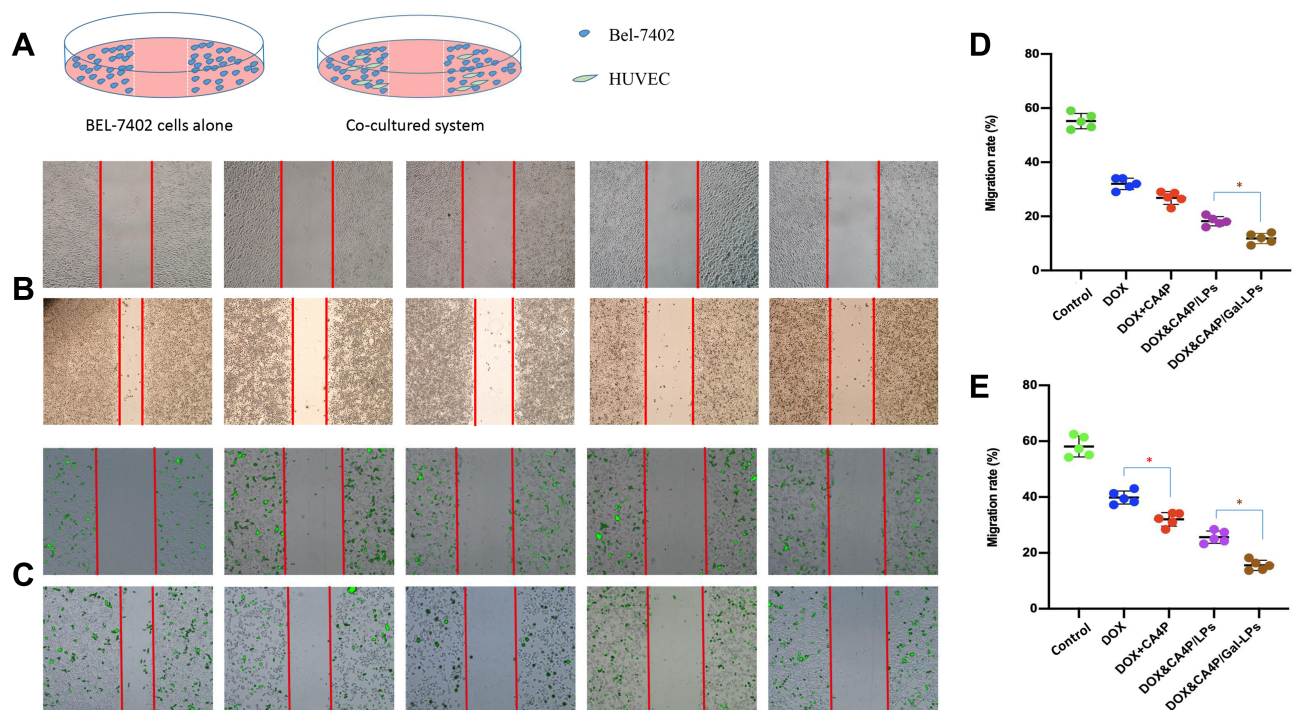

To evaluate the anti-migration effects of drug-loaded liposomes, 2D scratch assay was performed on the monolayer of BEL-7402 and co-cultured systems (Figure 5A). As shown in Figure 5B and C, compared to the control group, cell migration inhibition was observed in the cells treated with different drug formulations. As expected, the wound areas in liposomal formulation groups were less than that of free DOX, indicating that DOX&CA4P-loaded LPs showed a greater anti-migration ability than free DOX. Moreover,

**Figure 4** (A) In vitro anti-tumor model of BEL-7402 alone and co-cultured system of BEL-7402 and HUVEC cells. The cytotoxicity of different drug formulations against BEL-7402 alone (B) and co-cultured system (C), respectively. \*Value presents statistically significant difference ( $P<0.05$ ).

the degree of cell migration in DOX&CA4P/Gal-LPs was lower than that of mixture of DOX and CA4P or DOX&CA4P/LPs (Figure 5C and D), suggesting that Gal-modified LPs promoted the ability of inhibiting cell

migration.<sup>35</sup> Furthermore, as shown in Figure 5C, the green fluorescence-label cells were distributed in the co-cultured system, indicating that BEL-7402 and HUVEC cells could grow well together. Interestingly, a mixture of

**Figure 5** (A) The in vitro cell migration model of BEL-7402 cells alone and co-cultural system of BEL-7402 and HUVEC cells. Typical images of different treatment groups inhibiting cell migration of (B) BEL7402 cells and (C) co-cultured system (green colors represented CFSE-labeled HUVEC cells). The quantification of migration ability were presented as percentages of the wound area in (D) BEL7402 cells alone and (E) co-cultured system. \*Value presents statistically significant difference ( $P<0.05$ ).

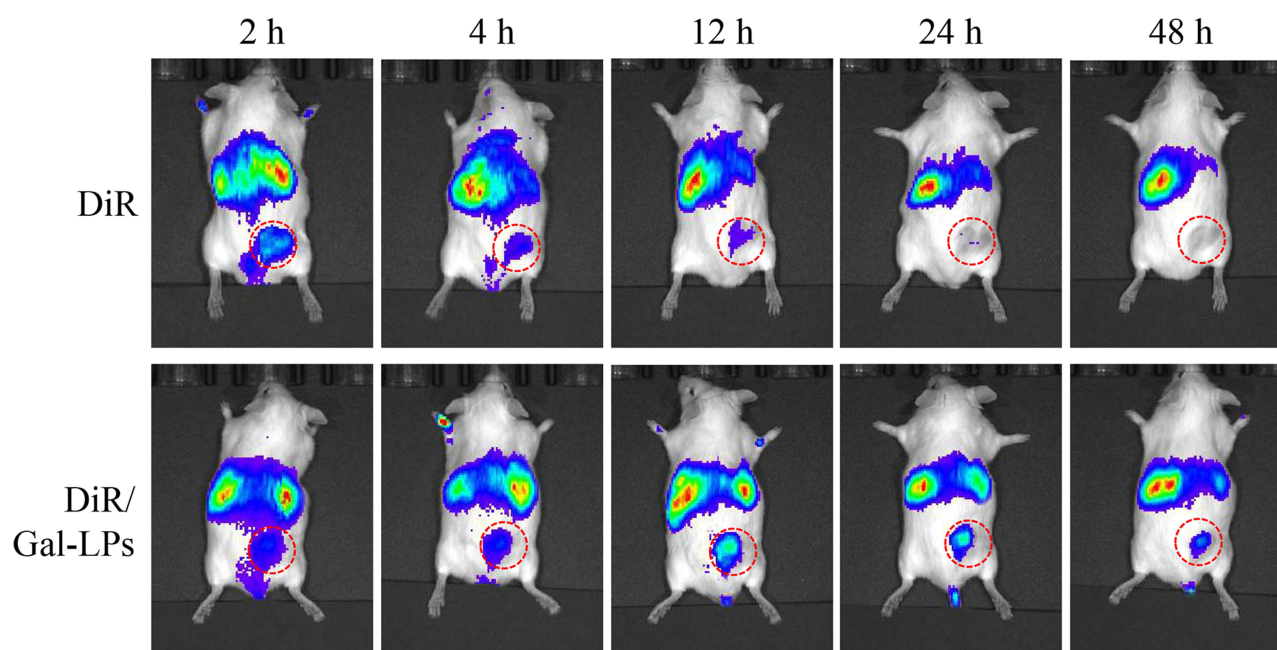

DOX and CA4P showed greater inhibition of cell migration than free DOX in the co-cultured system (Figure 5C and E), while there was no significant difference in the BEL-7402 cells alone, indicating that the co-cultured system was a more effective model to evaluate the anti-tumor activity of combined drugs in vitro. The results showed that combination therapy could exhibit stronger anti-migration effects by pro-apoptotic and anti-angiogenic activities.<sup>36</sup>

### In vivo Real-Time Imaging

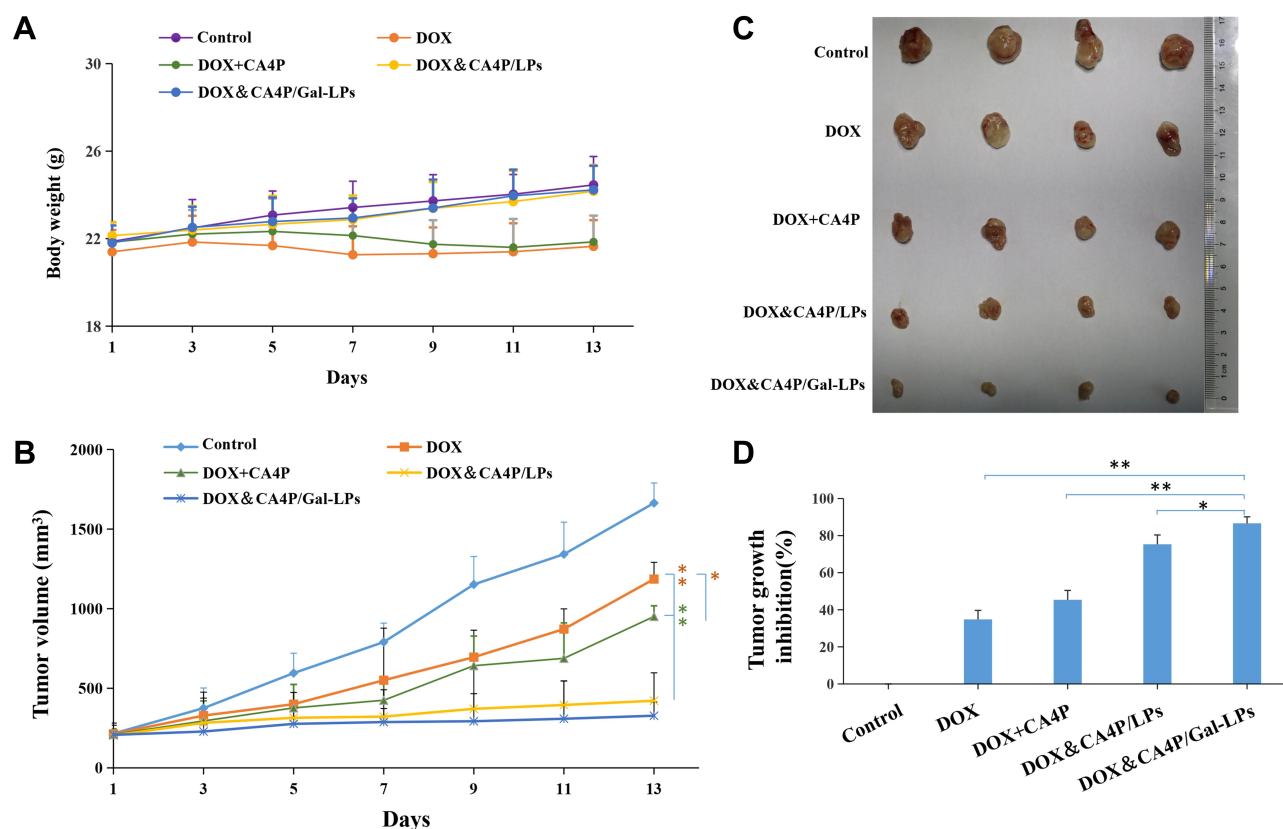

To investigate the bio-distribution of the drug in tumor-bearing mice, in vivo real-time NIRF imaging of DiR/Gal-LPs was observed. In this study, DiR, a fluorescence probe, was loaded into liposomes to mimic DOX. The intensity of the fluorescence signals represents the accumulation of the drug in mice. As shown in Figure 6, there was an obvious difference in the fluorescence intensity between free DiR and DiR/Gal-LPs group. At 2 hours, the fluorescence signals in the tumor region could be detected in two groups, and it became stronger in the DiR/Gal-LPs group at 12 hours compared with the free DiR group, suggesting that the Gal-LPs promoted DiR accumulation in the tumor. At 24 or 48 hours, the fluorescence signals in the Gal-LPs group were still strong, indicating the presence of amounts of DiR in the tumor region. In contrast, there was little fluorescence in the free DiR group. The results showed that Gal-LPs could enhance the drug accumulation in HCC, and keep sustained release at 48 hours.<sup>30</sup>

### In vivo Anti-Hepatoma Efficacy

Tumor proliferation and angiogenesis could promote tumor development, and the combination therapy with DOX and CA4P was used for anti-tumor therapy by proapoptotic and anti-angiogenic activities. The anti-hepatoma efficacy of drug-loaded liposomes was investigated on the H22 cell-bearing mice. As shown in Figure 7A, there were obvious decreases of body weight in the groups treated by free DOX or a mixture of DOX and CA4P in comparison with the saline group. By contrast, no significant difference was observed between the liposomal groups and the control group, suggesting that Gal-LPs were biocompatible, and could be used as the safe nano-sized carrier for delivery of anti-tumor drugs. It was shown that the anti-tumor effects of combined treatment groups (mixture of DOX and CA4P, DOX&CA4P/LPs, and DOX&CA4P/Gal-LPs) were stronger than that of the single drug group (free DOX), indicating that the addition of CA4P improved the inhibitory effect of DOX in anti-hepatoma therapy (Figure 7B and C). As anticipated, the tumor volumes of the mice treated with two liposomal formulations were smaller than the mixture of DOX and CA4P. The results were due to the fact that the nano-sized carriers could improve the drug accumulation in the tumor region via EPR effect, resulting in enhanced antitumor effects.<sup>37</sup> Furthermore, DOX&CA4P/Gal-LP showed superior anti-tumor effects among the four drug treatment groups (Figure 7D), suggesting that introduction

**Figure 6** NIRF images of H22 tumor-bearing mice treated with free DiR or DiR/Gal-LPs. Red circle indicates the tumor region.

**Figure 7** In vivo antitumor effects of different drug formulations. (A) The changes in the body weight of H22 cell-bearing mice; (B) Tumor growth curve during different drug formulations treatment; (C) Tumor images of different groups; (D) Tumor growth inhibition rate (n=4). \* $P < 0.05$ , \*\* $P < 0.01$ .

of Gal molecular promoted the cellular uptake of drugs, leading to superior anti-hepatoma efficacy.<sup>38,39</sup>

## Immunohistochemistry and Histological Analysis

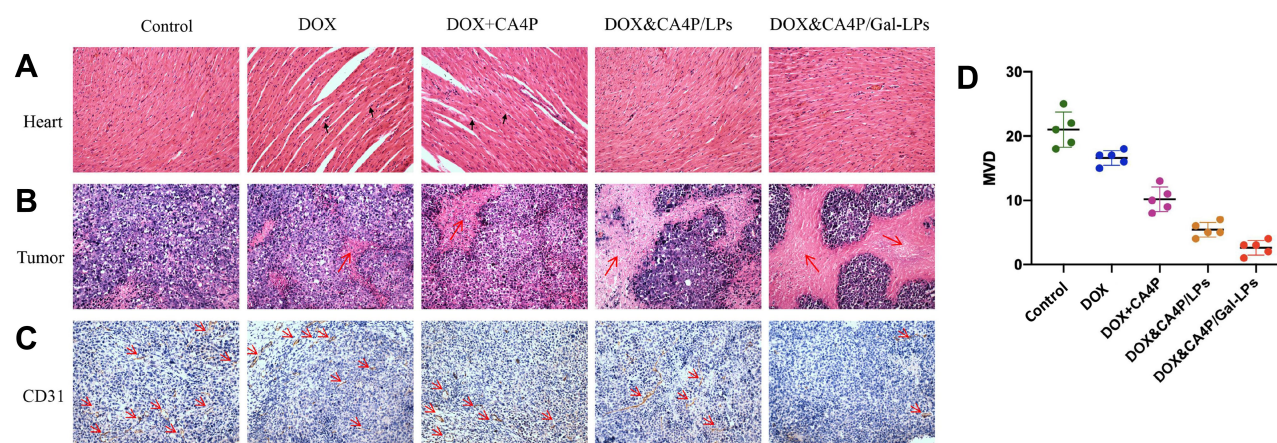

Systemic toxicity of DOX limited its clinical application. Compared with the control group, there was obvious intercellular vacuolation of myocardial fibers in the mice treated by free DOX or a mixture of DOX and CA4P (Figure 8A), suggesting traditional DOX formulation could induce severe cardiotoxicity. By contrast, the mice treated with liposomal formulations (DOX&CA4P/LPs, DOX&CA4P/Gal-LPs) showed no obvious degeneration of myocardial fibers, indicating that the nano-sized liposomes could decrease the systemic toxicity of DOX.<sup>40</sup>

The immunohistochemistry and histological analysis were further performed to evaluate the anti-tumor effects of combination therapy with DOX and CA4P. As shown in Figure 8B, more karyolytic and cytoplasmic vacuolization occurred in tumor areas in the drug-loaded liposomes groups than that in the traditional drug groups (free DOX, mixture of DOX and CA4P), indicating the nano-sized liposomes could improve the

anti-tumor efficacy. Additionally, the expression of CD31 (endothelial cell marker) was analyzed by immunohistochemistry. Figure 8C and D showed that there were fewer blood vasculatures in combined drug formulation groups than that in the single DOX group, indicating combination therapy with DOX and CA4P improved anti-angiogenic effects. Compared with DOX&CA4P/LPs, DOX&CA4P/Gal-LPs exhibited stronger inhibition of tumor angiogenesis, indicating that Gal-LPs could promote the anti-angiogenic effect via active-targeting delivery of DOX and CA4P.

## Conclusion

In this study, the novel Gal-modified liposomes (DOX&CA4P/Gal-LPs) were prepared for anti-hepatoma therapy through the combination of DOX and CA4P. DOX could act on tumor cells to promote the apoptosis of the tumor, while CA4P could perform the anti-angiogenic activities by acting on abnormal blood vessels in the tumor microenvironment. Meanwhile, the Gal molecule could specifically target the ASGP receptor, which is over-expressed on the surface of HCC cells, therefore improving the cellular uptake of liposomes, as well as improving the drug accumulation in tumor

**Figure 8** The histological images of Heart (A) and Tumor (B) by H&E staining; the Immunohistochemistry analysis by MVD images (C) and quantitative data (D). **Notes:** Black arrows indicate vacuolation of myocardial fibers in (A) and red arrows indicate tumor necrotic area in (B) and microvessels in (C), respectively.

region in vivo. The in vivo anti-tumor results showed that DOX&CA4P/Gal-LPs exhibited lower tumor angiogenesis, superior anti-proliferation efficacy, and less side-effects. On the other hand, to evaluate the combined anti-tumor effects, a novel co-cultured system composed of BEL-7402 and HUVEC cells was established. Compared with BEL-7402 alone, there were obvious differences in cytotoxicity and anti-migration effect between DOX and DOX+CA4P in the co-cultured system, indicating that the co-cultured system was an effective model for evaluation of combination therapy based on pro-apoptotic and anti-angiogenic activities. In summary, Gal-LPs were the potential liver-targeting nanocarriers, and the combination therapy of DOX and CA4P was a promising anti-tumor strategy for HCC treatment.

## Acknowledgments

This study was supported by the National Science Foundation of China (81803464), Natural Science Foundation of Shandong Province (ZR2019BH036), Science and Technology Development Project of Weifang (No. 2018YX058).

## International Journal of Nanomedicine

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-nanomedicine-journal>
