**Abstract:** Bempedoic acid is a first-in-class, oral, inhibitor of cholesterol biosynthesis that is approved for use in patients with atherosclerotic cardiovascular disease (ASCVD) and for primary prevention in individuals with heterozygous familial hypercholesterolemia (HeFH) by the United States Food and Drug Administration. Pooled data from the phase III clinical trials, CLEAR Harmony and CLEAR Wisdom, have demonstrated the safety and efficacy of bempedoic acid with regard to lowering of low-density lipoprotein cholesterol (LDL-C) in patients with HeFH as an adjunct or alternative to currently existing lipid-lowering therapies. CLEAR Outcomes is a cardiovascular outcomes trial that is currently underway that will provide additional insight as to where bempedoic acid will fit into treatment regimens among the non-statin lipid-lowering therapy options. Patients who might particularly benefit from bempedoic acid are those with HeFH and those unable to take adequate doses of statins or take any statin therapy altogether who need additional LDL-C lowering. In this review, we will discuss the profile of bempedoic acid from its design, development, and its place in therapy for the management of LDL-C for the purposes of ASCVD prevention.

**Keywords:** bempedoic acid, familial heterozygous hypercholesterolemia, lipids, atherosclerotic cardiovascular disease, prevention, low-density lipoprotein cholesterol

## Introduction

Heterozygous Familial Hypercholesterolemia (HeFH) is characterized by inherited elevations in low-density lipoprotein cholesterol (LDL-C) levels and is associated with a substantially increased risk for atherosclerotic cardiovascular disease (ASCVD).<sup>1</sup> HeFH patients carry mutations in one allele of the LDL receptor (*LDLR*), apolipoprotein B (*ApoB*), or proprotein convertase subtilisin/kexin type 9 (*PCSK9*) genes.

While statins have been the mainstay of therapy in these patients, statins alone are often unable to reduce LDL-C levels to the desired therapeutic threshold, and additional pharmacologic therapy may be needed to reduce ASCVD risk.<sup>2</sup> Furthermore, some patients are unable to tolerate sufficient or any statin therapy and need alternative pharmacotherapy for adequate LDL-C lowering. Current adjuncts or alternatives to statin therapy include ezetimibe and PCSK9 inhibitors.<sup>3,4</sup> Ezetimibe is oral, affordable, and well tolerated; as such, it is the next recommended LDL-C-lowering agent after statins. However, even with the combination of ezetimibe and maximally tolerated statin dose, many patients with HeFH remain above the LDL-C thresholds of 100 mg/dL (primary prevention) and 70 mg/dL (secondary prevention) where add-on therapy for additional LDL-C lowering would be recommended per recent guidelines.<sup>5</sup>

The 2018 American Heart Association (AHA)/American College of Cardiology (ACC)/Multi-society guideline for the management of blood cholesterol stated that for patients with severe primary hypercholesterolemia that remain above a threshold LDL-C  $\geq 100$  mg/dL despite statin plus ezetimibe therapy, in the setting of other ASCVD risk factors, a PCSK9 inhibitor would be reasonable.<sup>5</sup> The guideline also states that PCSK9 inhibitors are recommended for secondary prevention patients with ASCVD who remain at a threshold above 70 mg/dL despite therapy with statin plus ezetimibe.<sup>5</sup> Nevertheless, therapy with PCSK9 inhibitors is challenging, with greater costs and burdensome pre-authorization approvals in the United States, as well as subcutaneous injection creating barriers for some patients.<sup>6,7</sup> Thus, there is a need for alternative less expensive, effective, oral options for LDL-C lowering.

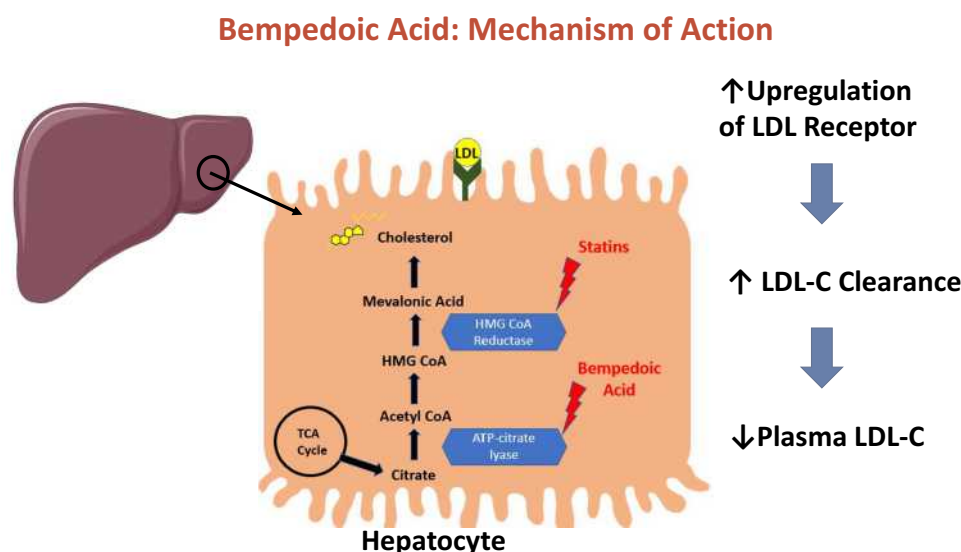

Bempedoic acid is a first-in-class, oral, small molecule inhibitor of cholesterol biosynthesis that functions in the same pathway as statins to lower LDL-C. Bempedoic acid was approved by the Food and Drug Administration (FDA) in February 2020 for use in the United States (US) as an adjunct to diet and maximally tolerated statin therapy for secondary prevention in patients with ASCVD and for primary prevention in individuals with HeFH, who require additional LDL-C lowering. This FDA approval was after the 2018 AHA/ACC Blood Cholesterol Guideline was published, and as such, bempedoic acid was not specifically addressed in prior guidelines.

## Mechanism of Action

Bempedoic acid inhibits adenosine triphosphate citrate lyase (ACL), a cytosolic enzyme that is highly expressed in lipogenic tissues and functions upstream of 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCoA reductase), the target of statin therapy (Figure 1). ACL inhibition decreases intracellular cholesterol biosynthesis and results in the upregulation of LDL receptors on hepatocytes, increasing uptake of LDL particles and ultimately reducing circulating LDL-C levels.<sup>8</sup> ACL plays a key role in linking energy metabolism from carbohydrates to the production of fatty acids because it catalyzes the cleavage of mitochondrial-derived citrate to cytosolic acetyl-CoA and oxaloacetate. Acetyl-CoA is the fundamental building block for de novo synthesis of cholesterol and fatty acids.<sup>9</sup> In a complex metabolism of cholesterol biosynthesis that is outside the scope of this review, two ACL-derived acetyl-CoA units are condensed to HMG-CoA by HMG-CoA synthase, and then reduced to mevalonate by action of HMG-CoA reductase.<sup>10</sup> Production of mevalonate is the rate limiting step in cholesterol biosynthesis. Statins are HMG-CoA reductase inhibitors.

Given its key role in cholesterol synthesis upstream of HMG-CoA reductase, ACL has been a potential target of therapeutic interventions. Prior efforts in *in vitro* inhibition of ACL have been unsuccessful, possibly due to the compounds' poor ability to cross cell membranes, reduced affinity for ACL, and nonspecific inhibition of other essential enzymes *in vivo*.<sup>10</sup>

Bempedoic acid is an oral, once-daily, small molecule with a half-life of 15–24 hours. It is rapidly absorbed in

**Figure 1** Bempedoic acid mechanism of action in the hepatocyte.

the small intestine and converted in the liver by an endogenous liver acyl-CoA-synthetase to a coenzyme A derivative. The active metabolite is responsible for the inhibition of ACL. In addition to ACL inhibition, bempedoic acid enhances the activity of 5' adenosine monophosphate-activated protein kinase (AMPK). AMPK activity inhibits the phosphorylation of acetyl-CoA carboxylase and HMG-CoA reductase, reducing both glucose and lipid biosynthesis, thereby contributing to LDL-C reduction via a different mechanism.

A series of genetic, pharmacologic and mouse models have shown that bempedoic acid has ACL and AMPK activities that occur only in cells that are capable of metabolizing bempedoic acid into its active form. In humans, the enzyme responsible for this, very-long-chain acyl-CoA synthetase-1 (ACSVL1) is expressed only by liver cells and not in skeletal muscle.<sup>11</sup> Indeed, *in vitro* studies have shown that bempedoic acid did not have any effect on cholesterol synthesis in muscle cells, nor did it induce muscle-related adverse effects in myotubes, compared with simvastatin or atorvastatin.<sup>11</sup> This is a potential mechanism by which bempedoic acid avoids the muscle-related adverse effects that are associated with statins, making bempedoic acid a particularly attractive option for patients with statin-associated muscle symptoms (SAMS).

## Preclinical Studies

Bempedoic acid (initially known as ESP-55016 and later as ETC-1002) was initially identified after chemical synthesis as  $\omega$ -hydroxy-alkanedicarboxylic acid (ESP-55016) and found to have remarkable lipid-lowering activity in female Zucker (fa/fa rats), a model of diabetic dyslipidemia.<sup>12</sup> Further investigations on ETC-1002 showed that this molecule acts as an inhibitor of ACL, now known to be its major mode of action.<sup>13</sup> In view of its complex mechanism, specific investigations on its properties were performed in primary human monocyte-macrophages and *in vivo* models of inflammation, which showed that bempedoic acid drives reduction in pro-inflammatory cytokines and chemokines.<sup>14</sup> More recent investigations were specifically targeted to animal models with hypercholesterolemia. For instance, bempedoic acid was shown to significantly reduce cholesterol and triglyceride levels as well as improve glucose tolerance in *Ldlr*<sup>-/-</sup> mice, in addition to a clear suppression of cholesterol ester accumulation in the aortas from treated animals.<sup>15</sup> Finally, the most definitive evidence of ACL

inhibition as the mechanism of action was provided by Pinkosky et al.<sup>11</sup> Bempedoic acid is activated by very-long chain acyl-CoA synthetase-1 (ACSVL1) to produce its downstream effects of inhibiting ACL, thereby reducing visceral adiposity, proinflammatory cytokines and chemokines, and atherosclerotic plaque size in mouse models.

## Phase I and II Clinical Trials

Fifteen phase I clinical trials evaluated the safety and tolerability of single and multiple doses of bempedoic acid in healthy individuals as well as those with mild dyslipidemia.<sup>16–18</sup> The results from phase I trials demonstrated on-treatment reductions in LDL-C levels ranging between 17% and 36%. No dose-related side effects were noted in phase I clinical trials.<sup>16–18</sup>

Ten Phase II clinical trials investigated the safety and efficacy of bempedoic acid in patients with hypercholesterolemia. Specific subpopulations explored in the phase II trials include patients with type 2 diabetes, statin intolerance, hypertension, on a background of either low- or high- intensity statin therapy, on a background of ezetimibe with and without statin therapy, and patients on a PCSK9 inhibitor (evolocumab).<sup>19–27</sup> Bempedoic acid was generally well tolerated across these trials and resulted in LDL-C lowering that ranged from 13% to 43%.<sup>19–27</sup>

## Phase III Clinical Trials

The efficacy and safety of bempedoic acid among patients with HeFH was assessed in two placebo-controlled Phase 3 studies: Cholesterol Lowering via Bempedoic Acid, an ACL-Inhibiting Regimen (CLEAR) Wisdom and CLEAR Harmony.<sup>28,29</sup>

CLEAR Harmony randomized patients with ASCVD with or without the presence of HeFH.<sup>28</sup> A total of 2230 patients with LDL-C levels  $\geq 70$  mg/dL taking maximally tolerated statin therapy were randomized to receive either bempedoic acid at a dose of 180 mg daily ( $n = 1487$ ) vs placebo ( $n = 742$ ) and followed for 52 weeks with a primary endpoint of safety and a secondary endpoint of percent change in LDL-C at week 12. It should be noted in this trial, that nearly 100% of the patients were taking statins and approximately 50% were on a high-intensity statin. At week 12, bempedoic acid demonstrated a 16.5% reduction in LDL-C compared to baseline and an 18.1% reduction compared to the placebo arm ( $p < 0.001$ ). Furthermore, there was an 11.9% reduction in apoB and a 21.5% reduction in high-sensitivity C-reactive protein (hsCRP) at week 12 compared to baseline ( $p < 0.001$  for both). These data confirmed the

safety and efficacy of bempedoic acid as an add-on to statin therapy regardless of background statin intensity.

CLEAR Wisdom enrolled adults with ASCVD with or without HeFH and LDL-C level  $\geq 70$  mg/dL on maximally tolerated lipid-lowering therapy.<sup>29</sup> The study randomized 779 patients to either 180 mg bempedoic acid or placebo once daily for a total of 52 weeks. The primary endpoint was percent change in LDL-C from baseline at week 12 of the study. Baseline LDL-C levels were 120 mg/dL, and treatment with bempedoic acid resulted in a 15.1% decrease in LDL-C levels at week 12 compared to baseline levels. Reductions were also noted in total cholesterol (TC) (9.9%), ApoB (9.3%), and hsCRP (median reduction of 18.7%). Patients receiving bempedoic acid vs placebo experienced a reduction of 15.1% vs a 2.4% increase, respectively (difference of 17.4%,  $p < 0.001$ ).

Pooled analyses from CLEAR Harmony and CLEAR Wisdom included a total of 3009 participants with ASCVD, of which 112 (3.7%) had a diagnosis of HeFH. The primary efficacy endpoint was mean percent change in LDL-C compared with baseline at week 12. Characteristics of patients from the pooled analysis with and without HeFH are shown in Table 1.<sup>30</sup> Baseline LDL-C levels were higher in individuals with HeFH ( $n = 112$ ; bempedoic acid, 144.1 [45.1] mg/dL; placebo, 156.5 [69.2] mg/dL) compared to those without HeFH ( $n = 2897$ ; bempedoic acid, 106.3 [30.9] mg/dL; placebo, 105.6 [30.0] mg/dL). At week 12, patients who received bempedoic acid exhibited a significant reduction in LDL-C levels with placebo-corrected reduction of  $-22.3\%$  (95%

CI  $-33.3, -11.4$ ) vs  $-18.3\%$  (95% CI  $-18.3, -16.6$ ) among individuals with and without HeFH, respectively ( $P < 0.001$ ).

Secondary efficacy endpoints included percent change at week 12 in non-high-density lipoprotein cholesterol (non-HDL-C), TC, ApoB, hsCRP, triglycerides (TGs), and HDL-C levels. Significant reductions were noted in non-HDL-C, TC, ApoB, and hsCRP in patients with HeFH treated with bempedoic acid vs placebo (Table 2).<sup>30</sup> Additionally, no differences were observed in the safety profile among individuals from CLEAR Harmony and CLEAR Wisdom with and without HeFH with regard to adverse events, serious adverse events, and adverse events leading to discontinuation of the drug.

The CLEAR Serenity trial examined bempedoic acid in patients with statin intolerance.<sup>31</sup> This trial enrolled 345 patients with hypercholesterolemia and a history of statin intolerance; 93% with a history of SAMS. This trial included 2% (7 out of 345) of patients with HeFH. At 12 weeks, bempedoic acid compared to placebo reduced LDL-C by 21% and hsCRP by 24%. Myalgias occurred less commonly with bempedoic acid than placebo (4.7% vs 7.2%).<sup>31</sup> There was no interaction between the primary outcome of change in LDL-C from baseline to week 12 by patient subgroups identified as primary prevention or secondary prevention/HeFH. These data support safety and efficacy of bempedoic acid among patients who cannot tolerate statins.

Bempedoic acid has also been evaluated in combination with ezetimibe in patients with hypercholesterolemia.<sup>32</sup> Out of 301 patients in the primary analysis (108 of which were randomized to the bempedoic acid ezetimibe fixed-dose combination), use of the fixed-dose combination of bempedoic acid 180 mg and ezetimibe 10 mg daily reduced LDL-C by 36.2% compared with bempedoic acid alone ( $-17.2\%$ ), ezetimibe alone ( $-23.2\%$ ) or placebo ( $+1.8\%$ ). Thus, the placebo-corrected difference for this fixed-dose combination was  $-38.0\%$ ;  $P < 0.001$ . Similar LDL-C reductions were seen across varying intensity of statins. The fixed-dose combination regimen also reduced hsCRP by 35.1%, which was greater than ezetimibe alone ( $-8.2\%$ ) or placebo ( $+21.6\%$ ). These data suggest that bempedoic acid and ezetimibe are more effective together in an additive manner, and the fixed-dose combination may be an attractive option for patients to reduce their overall pill burden.<sup>33</sup>

While LDL-C reduction is the primary target of therapy, there has been a consistently noted reduction in hsCRP with bempedoic acid. The Canakinumab Anti-

Inflammatory Thrombosis Outcome Study (CANTOS) showed that a therapy (canakinumab) that lowered inflammation (hsCRP) without influencing lipid levels also lowered ASCVD events.<sup>34</sup> Although canakinumab was ultimately not given FDA label approval for cardiovascular event reduction, CANTOS was a landmark study in proving the concept that targeting inflammation can reduce cardiovascular events in high-risk patients.

## Adverse Events/Safety

The most commonly reported treatment-related adverse effects were elevated uric acid levels, gout, myalgias, constipation, muscle spasms, fatigue, urinary tract infections, and oral discomfort across the phase III clinical trials of bempedoic acid. The studies also reported a slight increase in nasopharyngitis.<sup>29,32</sup> Myalgias were reported in approximately 1–7% of the patients across the phase III trials but were generally evenly distributed between the bempedoic acid and placebo arm.<sup>20–22</sup>

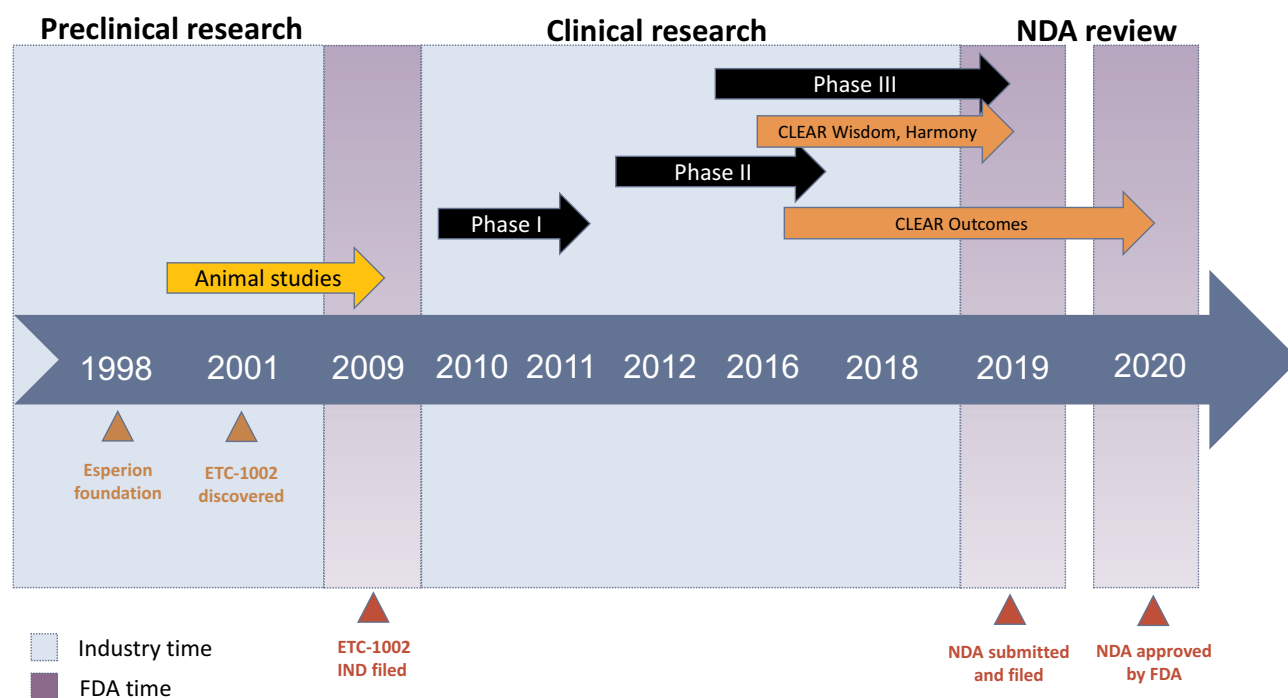

Uric acid levels and gout: In CLEAR Harmony, bempedoic acid was found to be associated with a modest increase in uric acid levels and gout cases. The incidence of gout was 1.2% vs 0.3% in the bempedoic acid vs placebo arms, respectively.<sup>28</sup> In CLEAR Wisdom, hyperuricemia was also seen more commonly with bempedoic acid (4.2%) than with placebo (1.9%).<sup>29</sup> Elevated uric acid levels were also seen with the fixed-dose combination (bempedoic acid plus ezetimibe), although there was not an increase in gout cases in that study.<sup>32</sup> Most cases of gout occurred in patients with a prior history of gout, and these data suggest caution, or at least additional monitoring of uric acid levels, in patients with a history of gout or at risk for gout.

Serious adverse events and death: No significant difference was found in serious adverse events, death, and cardiovascular mortality between the treatment and placebo arms across all of the phase III trials. Achilles tendon rupture occurred more frequently in patients treated with bempedoic acid (0.2% treated with bempedoic acid vs 0% of the patients treated with placebo).<sup>35</sup>

## FDA and Drug Development

An Investigational New Drug (IND) application was submitted by Esperion® in October 2009. Bempedoic acid has been evaluated in Phase 1 and Phase 2 clinical studies, and most recently in Phase 3 trials. Two New Drug Applications (NDAs) were submitted for bempedoic acid and the bempedoic acid/ezetimibe combination to the US FDA on February 20, 2019 and February 26, 2019, respectively. Simultaneously, Esperion® submitted two Marketing Authorization Applications (MAAs) to the European Medicines Agency (EMA) for bempedoic acid and bempedoic acid/ezetimibe combination on February 11, 2019.

Both NDAs received their first approval in the US (as monotherapy on February 21, 2020 and as the fixed-dose combination with ezetimibe on February 26, 2020) as an adjunct to diet and maximally tolerated statin therapy in adults with HeFH, or established ASCVD. In the European Union, bempedoic acid was approved for use in adults with primary hypercholesterolemia or mixed dyslipidemia in combination with ezetimibe (March 2020) and as monotherapy (April 2020). A summary of the timeline for this drug development is shown in Figure 2. On April 6, 2020, the European Commission approved the use of bempedoic acid for use in adults with primary hypercholesterolemia, as an adjunct to statin therapy, or as an alternative to statin therapy in those

**Figure 2** Timeline for the development of bempedoic acid.

**Notes:** Industry time is the time during which the industry or company was developing the drug, and FDA time refers to all the steps that were performed to get FDA approval.

**Abbreviations:** FDA, Food and Drug Administration; NDA, new drug application.

who are statin intolerant or in who statin therapy is contraindicated.

## Dosing and Dose Adjustment in Special Populations

The dosing of bempedoic acid is 180 mg orally once daily with or without food. No dose adjustment needs to be done for patients with mild or moderate kidney function impairment defined as having an estimated glomerular filtration (eGFR)  $\geq 30$  mL/min/1.73m<sup>2</sup>.<sup>36</sup> However, data are limited about the efficacy and safety of bempedoic acid in patients with eGFR less than 30 mL/min/1.73m<sup>2</sup> and the drug has not been studied in patients with end-stage kidney disease on dialysis. No dose adjustment needs to be done for patients with mild or moderate hepatic function impairment, but it has not been studied in patients with more severe liver disease (Child–Pugh score C).<sup>36</sup> Finally, in terms of older adults, among 3009 patients included in bempedoic acid clinical trials, 58% were aged  $\geq 65$  and 16% were aged  $\geq 75$ , and there were no significant differences in efficacy or safety between older and younger adults.<sup>36</sup> Bempedoic acid should not be administered concomitantly with either a simvastatin dose greater than 20 mg or a pravastatin dose greater than 40 mg due to the concern for statin-related myopathy.<sup>37</sup>

## Current and Potential Role in Therapy

While the efficacy of bempedoic acid appears to be weaker than that of high-intensity statins, it may be a useful adjunct in individuals who achieve less than desirable LDL-C reductions with statins or who cannot tolerate statins, where bempedoic acid alone or in combination with ezetimibe may be useful alternatives. Although the FDA label currently states that bempedoic acid treatment is specifically indicated for patients with HeFH or established ASCVD who need additional lowering of LDL-C, the tolerability and safety profile of bempedoic acid suggest its potential for the use in primary prevention beyond HeFH, such as those with statin intolerance. The effect of bempedoic acid on major adverse cardiovascular events (MACE) is unknown and currently being addressed in an ongoing cardiovascular outcomes trial (described below).

## Cardiovascular Outcomes Trial

CLEAR Outcomes is a phase 3 randomized, double-blind, placebo-controlled trial designed to assess the effects of bempedoic acid on major cardiovascular events in patients with or at high risk for cardiovascular disease and statin intolerance.<sup>38</sup> The trial began in December 2016 and has

completed recruitment,<sup>39</sup> with a targeted completion date of March 2022. The estimated enrollment size is 12,600, and participants were randomized to bempedoic acid 180 mg once daily vs placebo. The primary outcome is the time from randomization to the first occurrence of a composite cardiovascular endpoint of cardiovascular death, nonfatal myocardial infarction, nonfatal stroke, or coronary revascularization. Findings from CLEAR Outcomes will provide additional insight on the role of bempedoic acid and how it fits into the ever-growing armamentarium of lipid-lowering therapeutics.

There is overwhelming evidence from genetic studies, observational studies, and randomized clinical trials that support the notion that LDL-C is causally related to ASCVD and that LDL-C-lowering reduces ASCVD risk, particularly in higher risk patients.<sup>40,41</sup> Extrapolating from other studies, in a meta-analysis by Silverman et al evaluating other non-statin interventions that work primarily through upregulation of LDL-C receptor (diet, bile acid sequestrants, ileal bypass, and ezetimibe), there was a 23% reduction in major vascular events per 1 mmol/L (39 mg/dL) of LDL-C lowering (HR 0.77).<sup>42</sup> This was similar to the degree of reduction (25%) in vascular events per 1 mmol/L (39 mg/dL) of LDL-C lowering conferred by statins (HR 0.75).<sup>42</sup> Since bempedoic acid is a non-statin that also similarly works through a mechanism of upregulation of LDL-C receptor, we anticipate similar degrees of reduction in vascular events proportional to that same degree of LDL-C lowering. Thus, while we await confirmation from CLEAR Outcomes to be certain, it is anticipated that given its ability to reduce LDL-C, it will likely also reduce ASCVD.

## Conclusion

Bempedoic acid has demonstrated promise as a novel oral agent for LDL-C lowering as an alternative or adjunctive therapy for primary prevention in patients with HeFH and for secondary prevention patients. Pooled analyses from CLEAR Harmony and CLEAR Wisdom demonstrate ample scope for LDL-C lowering in this subgroup of patients even on a background of statin therapy. Furthermore, statistically significant reductions were noted in the secondary endpoints of non-HDL-C, total cholesterol, ApoB, and hsCRP. Overall, bempedoic acid appears to be safe, effective, and well tolerated among patients with HeFH, as well as patients with ASCVD. Bempedoic acid has now been FDA-approved as an adjunct to diet and maximally tolerated statin specifically for these patients – HeFH and ASCVD – who require

further LDL-C lowering. However, although not FDA-approved for this purpose, bempedoic acid may also hold promise as another useful agent in the toolkit for reducing LDL-C in primary prevention patients without HeFH who have statin intolerance, but this needs further study. We await the results from the large ongoing cardiovascular outcome trial (CLEAR Outcomes) to confirm the efficacy of bempedoic acid in reducing MACE.

**Drug Design, Development and Therapy**

Dovepress

**Publish your work in this journal**

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also

been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
