Introduction: To examine the factors associated with PAD, with a specific focus on bone metabolism factors such as osteocalcin.

Methods: This cross-sectional study examined factors about demographic, clinical, and laboratory parameters including bone metabolism biomarkers in hemodialysis patients. The ankle-brachial index (ABI) was measured in all patients, with PAD diagnosed as an ABI <0.9.

Results: Out of the 71 patients, PAD was found in 23 individuals. These patients had an average age of 63.5±13.0 years, with 59.2% being male. Compared to non-PAD patients, those with PAD were older, had a lower proportion of males, and had a higher prevalence of diabetes and coronary artery disease. Among the factors related to bone metabolism, only osteocalcin exhibited a significant increase in the PAD group compared to the non-PAD group.

Conclusion: PAD in patients on hemodialysis was independently linked to high levels of osteocalcin in the bloodstream, indicating the presence of bone metabolism disorders.

Keywords: hemodialysis, osteocalcin, bone metabolism disorder, peripheral artery disease

Introduction

Peripheral artery disease (PAD) is a chronic medical condition that is becoming more common worldwide and is associated with a poor outlook.¹⁻³ Recent study revealed that inflammation was associated with acute and chronic PAD as detected by neutrophils / lymphocyte ratio. Moreover, there were studies showed that inflammatory burden was increased as renal dysfunction progressed and predicted adverse clinical prognosis in hemodialysis patients.^{4,5} Thus, the development of PAD seems to be related to renal dysfunction. The diagnosis of PAD using the ankle-brachial index (ABI) is more prevalent in individuals undergoing hemodialysis and has been linked to the prediction of cardiovascular disease and overall mortality.² The Dialysis Outcomes and Practice Patterns Study (DOPPS) collected data indicating that approximately one-third of patients on hemodialysis suffer from PAD, which significantly increases the risks of both illness and death compared to the general population.⁶ Despite numerous studies investigating potential risk factors for PAD, these factors have not been adequately explored in patients undergoing hemodialysis. The involvement of abnormal bone metabolism in the development of cardiovascular disease, particularly in patients on hemodialysis, has been a well-known fact for a considerable period.⁷ Due to the distinct combination of biochemical, endocrine, and molecular irregularities in bone metabolism disorders specific to these patients, there is evidence indicating a consistently higher prevalence of systemic atherosclerosis, including PAD.⁸ A previous study conducted on patients on hemodialysis in Central Nepal revealed a significant and independent association between PAD and levels of intact parathyroid hormone exceeding 300 ng/mL.⁹ However, a subsequent study yielded conflicting results.¹⁰ Although a few studies have examined the predictive role of calcium and phosphate metabolism biomarkers for PAD in patients on hemodialysis,^{11,12} the

available information remains insufficient and contradictory. The objective of this study was to investigate the factors associated with PAD in individuals undergoing hemodialysis and to assess the influence of bone metabolism, specifically osteocalcin serum levels, in these patients.

Materials and Methods

Patients

We included participants in our study who were patients on hemodialysis, aged 18 years or older, and received treatment at Beijing Jishuitan Hospital, Capital Medical University from April 2021 to April 2022. The treatment regimen consisted of three sessions per week, each lasting four hours. All the patients in the study underwent treatment for regulating calcium-phosphorus levels such as Vitamin D Receptor Activators and calcimimetics and were monitored by qualified staff. Patients with a duration of hemodialysis of less than six months, as well as those with severe infections or malignancy, were excluded from the study.

The Institutional Review Board of Beijing Jishuitan Hospital, Capital Medical University granted approval for this study, and the procedures followed in the study adhered to the principles outlined in the Declaration of Helsinki. Prior to their participation in the study, written informed consent was obtained from all patients.

Demographic and Clinical Characteristics

The medical records of the enrolled patients were examined. We gathered information on various demographic factors such as gender, age, and body mass index (BMI). Additionally, we recorded specific details related to hemodialysis, including primary kidney disease, duration of hemodialysis, dialysis adequacy, and the presence of diabetes mellitus (DM), coronary artery disease or fractures. Dialysis adequacy was assessed using Kt/V, while BMI was calculated using the formula weight/height^2 (kg/m^2).

Laboratory Parameters

The patients' laboratory values were regularly assessed on a monthly basis, encompassing various parameters such as serum albumin, potassium, sodium, uric acid, triglyceride, total cholesterol, hemoglobin levels, and C-reactive protein (CRP). Additionally, bone-related parameters, including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D (25[OH]D), and osteocalcin, were also routinely evaluated each month. These measurements were conducted at the Clinical Laboratory of Beijing Jishuitan Hospital, Capital Medical University, and the data was obtained from the electronic clinical database.

ABI Measurements

The ABI values were determined by the same skilled doctor using a portable handheld bidirectional Doppler device and was conducted within one week after blood test. The patients were positioned on their backs, and monitoring cuffs were attached to appropriate areas. The doctor measured the systolic blood pressure in the brachial artery of the arm without vascular access, as well as in the dorsalis pedis artery and posterior tibial artery of both lower limbs using a Doppler probe. To calculate the ABI values, the systolic pressure at the ankle was divided by the systolic pressure in the arm. The lower ABI value from both legs was considered the leg index. The diagnosis of PAD was based on an ABI value below 0.9, which is in line with the guidelines provided by the American College of Cardiology/American Heart Association and consistent with previous studies.^{2,12–14}

Statistical Analysis

The mean±standard deviation or median value and interquartile range were used to express continuous variables, depending on the distribution of the data. Numbers and percentages were used to express categorical variables. The comparison of continuous variables was done using Student's *t*-test and the Mann–Whitney *U*-test, while the chi-square test was used for comparing categorical variables. To examine the relationship between the variables and PAD, multivariate logistic regression models were created, including only those variables that showed statistical significance in the

univariate analyses. The correlation between osteocalcin and these variables was also tested using Spearman's Rank-Order Correlation. A P value < 0.05 was considered statistically significant. All statistical analyses were conducted using SPSS software for Windows (version 25.0; SPSS, Chicago, IL, USA).

Results

In the study, a total of 71 patients were included. Their average age was 63.5 ± 13.0 years, with 40.8% being female and 59.2% male. These patients had been undergoing dialysis for an average duration of 75.2 ± 50.0 months. Among them, 23 patients were identified as having PAD and were assigned to the PAD group, while the remaining 48 patients were classified as the non-PAD group. The baseline characteristics of the patients are provided in Table 1. The most common cause of end-stage renal disease (ESRD) was diabetes mellitus (36.6%), followed by glomerulonephritis (25.4%). When comparing the PAD group with the non-PAD group, it was found that the PAD patients were older (72.2 ± 10.9 vs 59.3 ± 11.9 years, $p < 0.001$), had a lower percentage of males (47.8% vs 64.4%, $p < 0.001$), and a higher prevalence of diabetes mellitus or coronary artery disease (56.5% vs 31.3%, $p < 0.001$; 65.2% vs 27.1%, $p < 0.001$, respectively). Eight patients had history of fracture, three were in the PAD group and five were in the non-PAD group without statistic significant difference (13.0% vs 10.4%, $p = 0.872$). No statistically significant differences were found between patients with or without PAD in terms of the traditional markers related to bone metabolism. These markers include phosphate (1.54 ± 0.44

Table 1 Baseline Characteristics of Study Population

Table 2 Univariate and Multivariate Analysis for Peripheral Arterial Disease

Independent Variable	Univariate Model		Multivariate Model	
	OR (95% CI)	P	OR (95% CI)	P
Age	0.92 (0.84–1.00)	0.047	1.08 (0.98–1.19)	0.127
Duration of hemodialysis	0.99 (0.98–1.01)	0.031	1.00 (0.99–1.02)	0.442
Diabetes mellitus	3.29 (0.51–21.24)	0.021	1.16 (0.14–9.45)	0.889
CAD	0.66 (0.10–4.51)	0.018	0.29 (0.04–2.00)	0.208
Osteocalcin	1.04 (1.01–1.09)	0.005	1.03 (1.00–1.05)	0.021

Abbreviations: CAD, coronary artery disease; OR, odds ratio; CI, confidence interval.

Table 3 Correlation Between Osteocalcin and Other Factors

Variable	R	P
Age	−0.140	0.366
Duration of hemodialysis	0.252	0.099
Diabetes mellitus	−0.145	0.347
CAD	0.179	0.244

Abbreviation: CAD, coronary artery disease.

vs 1.53±0.45, p=0.908), calcium (2.29±0.11 vs 2.24±0.15, p=0.138), intact parathyroid hormone calcium (286.07±35.82 vs 235.39±36.52, p=0.393), and 25(OH)D (11.61±5.44 vs 13.74±6.13, p=0.166). However, there was an increase in osteocalcin levels in the PAD group compared to the non-PAD group (166.07±11.34 vs 118.04±15.33, p=0.017) as shown in Table 1. A single-variable analysis revealed a significant correlation between PAD and various factors such as age, duration of dialysis, diabetes mellitus (DM), coronary artery disease, and osteocalcin level. However, other indicators of bone metabolism did not exhibit any association with PAD. Subsequent multivariable analyses demonstrated that only osteocalcin remained an independent risk factor for the development of PAD. The odds ratio (OR) for osteocalcin was 1.03 with a confidence interval (CI) of 1.00 to 1.05 and a p-value of 0.021, indicating its significant impact (Table 2). No significant relationship was found between osteocalcin and these factors (Table 3).

Discussion

This research aimed to examine the factors associated with PAD in patients on hemodialysis. Previous study showed that PAD patients undergoing popliteal and infrapopliteal percutaneous peripheral arterial interventions with renal dysfunction (GFR<60 mL/min/1.73 m2) and hemodialysis had increased risk of major amputations and mortality. This study called for novel therapeutic strategies to improve outcomes of this population.¹⁵ Specifically, our study revealed that the bone metabolism marker osteocalcin exhibited an independent correlation with PAD. To the best of our knowledge, this is the first study to establish a connection between PAD and bone metabolism in patients on hemodialysis, considering the unique bone metabolism disorder in this population that may contribute to vascular calcification. Numerous studies conducted over the past few decades have endeavored to identify predictive factors for PAD. Age, female gender, body mass index, critical limb ischemia, diabetes mellitus, hypertension, cerebrovascular disease, heart failure, and chronic kidney disease (CKD) have been associated with poor limb salvage, mortality, or readmission following peripheral revascularization in patients with or without hemodialysis.^{16–20} Recent studies have further demonstrated that patients undergoing hemodialysis are more susceptible to PAD and experience worse outcomes.^{8,14,21–26} Cross-sectional studies have reported a high prevalence of PAD in patients on hemodialysis and have identified lower serum albumin levels, elevated C-reactive protein levels, Hickman vascular access, and foot deformity as independent predictors of PAD or foot ulceration in these patients.^{10,12} However, a prospective study involving 450 dialysis patients only found neuropathy and previous ulceration to be significant risk factors for foot ulceration, while serum albumin and C-reactive protein levels showed no significant association with this condition.²⁷ Risk factors also varied between patients with and without prior ulceration. Raikou et al²⁸ conducted an analysis of 150 patients undergoing on-line-predilution hemodiafiltration and discovered

that low-grade inflammation, as indicated by elevated monocyte chemoattractant protein-1 serum concentrations was a significant predictor for PAD. This biomarker has long been recognized as a key mediator of osteoclastogenesis in HD patients with PAD, which suggested an association between inflammatory response and bone metabolism. But the relationship between bone metabolism, especially the osteocalcin and PAD was not discussed by the authors. Another study involving peritoneal dialysis patients demonstrated that osteoprotegerin was an independent predictor of PAD, establishing a link between bone metabolism and arterial calcification.¹³ Collectively, while these previous studies identified both traditional and novel risk factors, the findings were not consistent, and most factors were non-intervenable. In line with previous research, our study focused on a group of hemodialysis patients with a low ABI. These patients tended to be older, more likely to be female, and had a higher prevalence of diabetes mellitus or coronary artery disease compared to those with a normal ABI. We examined bone metabolism and found that commonly used indicators such as phosphate, calcium, intact parathyroid hormone, and 25(OH)D did not show any significant differences between hemodialysis patients with PAD and those without PAD.

Bone metabolism disorders have long been linked to arterial calcification, which can lead to PAD. Previous studies, such as the NEFRONA study,¹¹ have noted lower levels of 25(OH)D in patients with CKD with an ABI ≤ 0.9 . A meta-analysis also revealed reduced 25(OH)D levels in non-hemodialysis patients with PAD, suggesting it could be an independent risk factor for PAD.²⁹ However, a recent study from China found no association between vitamin D deficiency and PAD in middle-aged and elderly diabetic patients. The authors attributed this inconsistency to age differences, as the expression level of the vitamin D receptor decreases linearly with age.³⁰ Notably, our study also observed that patients with PAD were older than those without, consistent with these findings.

Another study by Hsu et al³¹ reported that parathyroidectomy reduced the risk of PAD in patients on hemodialysis with severe secondary hyperparathyroidism, possibly by lowering parathyroid hormone levels. However, subsequent studies in patients on hemodialysis with PAD found no significant differences in intact parathyroid hormone and 25(OH)D levels, as well as phosphate and calcium levels.^{10,27,32,33} These results align with our study's findings. The lack of variation in traditional bone metabolism markers may be attributed to severe mineral metabolism abnormalities or the increased use of phosphate binders and vitamin D supplements in patients on hemodialysis, which might have masked the differences. The current study made an important discovery regarding the relationship between high levels of osteocalcin and PAD in patients on hemodialysis. Osteocalcin, a factor produced by osteoblasts primarily involved in bone mineralization, was found to have additional functions beyond bone regulation, including effects on the pancreas, liver, muscle, adipose tissue, testes, vascular system, as well as the central and peripheral nervous system. This indicates that osteocalcin has an endocrine role outside of the skeletal system.^{34,35}

A study conducted by Wu et al³⁶ demonstrated that osteocalcin can protect against neuronal loss and improve outcomes in patients with acute ischemic stroke. This effect is attributed partly to the inhibition of proline hydroxylase 1 and prevention of gasdermin D degradation. Another clinical study on PAD in patients revealed that bone-like structures containing osteocalcin were present in heavily calcified blood vessels.³⁷

Furthermore, both laboratory experiments and studies in living organisms have shown that osteocalcin is involved in the regulation of vascular calcification through the Wnt/ β -catenin signaling pathway and glucose metabolism.^{38,39} Therefore, the increased levels of osteocalcin observed in this study may indicate an interaction between bone metabolism and vascular calcification, or it could suggest that osteocalcin itself plays a significant role in this process. However, further research is needed to fully understand the underlying mechanism involved. The current investigation had certain constraints. To begin with, it employed a cross-sectional approach and involved a restricted number of patients that might resulted in a weak relationship of osteocalcin with PAD. Secondly, bone turnover markers collected in this study was limited because other markers were not routinely tested in our hemodialysis center. Despite these limitations, our study provides significant understanding regarding the connection between bone metabolism and PAD in patients on hemodialysis. Additional studies with a larger sample size, collected more biomarkers and long-term follow-up are necessary within this population to draw definitive conclusions.

Conclusion

To summarize, the study concluded that there is a significant association between serum osteocalcin levels and PAD in patients undergoing hemodialysis. Traditional markers for bone metabolism did not demonstrate enough sensitivity.

These findings suggest that osteocalcin may play a role in the development of PAD in patients on hemodialysis, although the exact mechanism requires further investigation.

Diabetes, Metabolic Syndrome and Obesity

Dovepress

Publish your work in this journal

Diabetes, Metabolic Syndrome and Obesity is an international, peer-reviewed open-access journal committed to the rapid publication of the latest laboratory and clinical findings in the fields of diabetes, metabolic syndrome and obesity research. Original research, review, case reports, hypothesis formation, expert opinion and commentaries are all considered for publication. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
