Application of reticulated platelets to transfusion management during autologous stem cell transplantation

Background: The immature (or reticulated) platelet fraction (IPF) is rich in nucleic acids, especially RNA, and can be used as a predictive factor for platelet recovery in platelet immunomediated consumption or in postchemotherapy myelosuppression. Our aim was to determine if transfusions with IPF-rich solutions, during autologous peripheral blood stem cell transplantation, reduce the occurrence of bleeding and hemorrhagic complications.

Patients and methods: Transfusions were administered to 40 children, affected with hematological pathologies, who underwent autologous peripheral hematopoietic progenitor cell transplantation. There were two groups of 20 patients, one group treated with IPF-poor and the other with IPF-rich solutions. In the two groups, the conditioning regimen was the same for the same pathology (hematological pathologies: 14 acute lymphoblastic leukemia; twelve acute myelocytic leukemia; four non-Hodgkin’s lymphoma; two Hodgkin’s lymphoma; eight solid tumors). A new automated analyzer was used to quantify the IPF: the XE2100 (Sysmex, Kobe, Japan) blood cell counter with upgraded software.

Results: The 20 patients who received solutions with a high percentage of IPF (3%–9% of total number of infused platelets) required fewer transfusions than the 20 patients who received transfusions with a low percentage of IPF (0%–1% of total number of infused platelets): 83 versus 129 (mean of number of transfusions 4.15 versus 6.45) and a significant difference was found between the two groups by using the Mann–Whitney test ($P < 0.001$). The prophylactic transfusions decreased from three to two per week. There was only one case of massive hemorrhage.

Conclusion: The use of IPF solutions reduces the number of transfusions and bleedings after peripheral blood stem cell transplantation in pediatric patients.

Introduction
Immature (or reticulated) platelets (PLTs) contain more RNA than mature PLTs and their number in peripheral blood reflects the rate of thrombopoiesis. Immature PLTs are more active than nonreticulated PLTs because of their higher nucleic acid content and higher expression of P-selectin and glycoprotein. New automated, US Food and Drug Administration-approved methods have been developed to count immature PLTs. The immature PLT fraction (IPF) count is a useful index of thrombopoiesis, which increases when the IPF rises and decreases when the IPF declines.

The IPF count reflects peripheral PLT destruction that results from the suppression of bone marrow production and can be used as a predictive factor for PLT recovery.
Materials and methods

Over a 2-year period, two groups of 20 children (aged 5–18 years) received transfusions with either IPF-poor solutions or with IPF-rich solutions, during autologous peripheral blood stem cell (PBSC) transplantation, according to the EU procedures, as reported in the manual for transfusions at our hospital. In the two groups, the conditioning regimen was the same for the same pathology (hematological pathologies: 14 acute lymphoblastic leukemia, twelve acute myelocytic leukemia (AML), four non-Hodgkin’s lymphoma, two Hodgkin’s lymphoma, eight solid tumors). Young patients were classified as follows: (1) stable and receiving prophylactic therapy, having a PLT count < 10,000/µL; (2) having mucosal hemorrhage with a PLT count < 50,000/µL; (3) exhibiting signs of active bleeding from insertion catheters with a PLT count between 50,000 and 100,000/µL; (4) experiencing massive blood loss with a PLT count of < 50,000/µL. Before entering this study an informed consent form was delivered to all patients (or their parents), which was approved by the Ethics Committee of the Hospital; only one patient did not return the consent form.

The IPF is donor dependent (range in human blood: 0.3%–7.0% of total PLT). The blood donors in our study were selected according to European regulations. A blood cell separator (Haemonetics MCS Plus version C, Haemonetics Corp, Baintree, MA) was used, with multicomponent collection kits. After collecting standard PLT, a chemiluminescence method (Abbott, Milan, Italy) was implemented to aid in the treatment of possible coagulopathy. We used the Procleix Ulitro (Chiron Ltd, Emeryville, CA) test kit-based transcription-mediated amplification for nucleic acid amplification testing studies of serum samples from donors (human immunodeficiency virus, hepatitis C virus, and hepatitis B virus). Otherwise, we used a new automated instrument, the XE-2100 (Sysmex, Kobe, Japan), with a modern routine, fully automated analyzer and upgraded software. The thrombelastograph (Medival, Padua, Italy) was implemented to aid in the treatment of active hemorrhage and approved by the Ethics Committee of the Hospital; only one patient did not return the consent form.

In this study, we tested the efficacy of transfusions in pediatric patients, who underwent autologous peripheral hematopoietic progenitor cell transplantation, with PLT concentrates (PCs) enriched with young and more active PLTs (IPF). We determined whether this treatment reduced the occurrence of massive or mucosal hemorrhage during the post-transplantation period.

The study design was to evaluate the relationship between two groups of transfusions, one with IPF-poor and the other with IPF-rich solutions stored for the same time and similarly administered in terms of transfusion frequency, and the development of hemorrhagic or transfusion-transmitted complications. We also aimed to verify the utility of a new automated hemoanalyzer to count the IPF in donors and in PCs and to study the outcome in patients.

harvested were sent to a dry PC bag, withdrawn by a syringe, and counted with the XE-2100 analyzer. The contents of the separation chamber were then driven into the standard PC bag, to avoid plasma contamination, and then into a PC bag containing additive storage solution (T-SOL; Baxter, Deerfield, IL). After collection, both plasma PC and PC with T-SOL were left undisturbed for 1 hour. For sampling, the plasma PC was connected to a 100 mL transfer bag using a sterile connection system and approximately 15 mL was withdrawn for analysis. The other bag contained a mean of $3.0 \pm 0.2 \times 10^{11}$ PLTs, and was preserved in T-SOL at 23°C for no longer than 2 days to avoid changes of numbers over time.11 The PCs were leukodepleted by MachoPharma filters (Mouvaux, France) to avoid immunologically mediated effects, further possible bacterial contaminations, and infectious disease transmission (cytomegalovirus, human T-lymphotrophic virus Type I and II).12–14 Finally, they were also treated by a gamma irradiator for 6 minutes, at the time of transfusion.16,17 The treatment and checking of the two groups were similar. Physicians and patients understood and approved the treatment with IPF. The data were analyzed using a nonparametric statistical test and the Mann–Whitney test in order to overcome the underlying assumption of normality in parametric tests with small sample and because the two samples under consideration may not necessarily have the same number of observations. The conditions of the patients were stabilized about the main parameters (stable Hb; normal coagulation tests; general satisfactory health without fever, cough or infections).

**Results**

In this report only the first two categories, PLT count $<10,000/\mu$L (prophylactic therapy) and PLT count $<50,000/\mu$L (mucosal hemorrhage), were evaluated, for a total number of 40 patients. Twenty received transfusions of $3.0 \times 10^{11}$ PLTs with a low IPF level (0%–1% of total infused PLTs) and the other 20 received IPF-rich transfusions (3%–9% of total infused PLTs). The dose of infused IPF was different, in accordance with the patient’s weight: $3.0 \pm 0.2$ for children of 40–60 kg; $1.5 \pm 0.2$ for children of 20–39 kg (Table 1). In this second case, the remaining half dose of IPF was used to prepare heterologous PLT gel to cure skin ulcers, sores, and bone degeneration in other patients.

The data show that the efficacy of transfusion in the 20 patients who received rich IPF was higher than that of low IPF transfusion (Tables 2 and 3). There was only one case of massive blood loss post-transplantation versus three in the low IPF group and no cases of mucosal hemorrhage. The number of transfusions was lower for patients receiving rich IPF than low IPF solutions and the rich IPF decreased the need for prophylactic transfusions from three to two per week (Figure 1). The timing of engraftment and patient outcome were the same (mean of 10 days $\pm 3$) for patients

| Patients | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |

receiving autograft transplants, and there were no cases of hemorrhage, bacterial contamination due to management and counting of IPF, transfusion-transmitted infections, or other health-related complications.\(^{18-23}\) We used the Mann–Whitney test to compare the number of transfusions between the two groups of patients and pathologies (because it is a nonparametric statistical test), and a significant difference was observed (Table 4). The initial health conditions before transplantation were similar, including stable hemoglobin values, normal coagulation tests, and general satisfactory health.

**Conclusion**

The exclusion and inclusion criteria of the study excluded only three cases (fever and cough) and one IPF transfusion (PLT clumps in the bag), as European Bone Marrow Transplantation criteria prescribe for a trial.\(^ {14}\) The processing time to control IPF dosage was relatively short (5 minutes) and did not affect the cost of the procedure. This counting is essential during the last cycle of PLT apheresis, to determine whether the collected plasma has a high percentage of reticulated PLTs during the last cycle of PLT apheresis, to determine whether the collected plasma has a high percentage of reticulated PLTs in hemostasis, compared to mature PLTs, encouraged these studies.\(^ {30-32}\)

It is critical also to choose the dosage and the use of IPF as a prophylactic approach to lower the chances of post-transplantation bleeding, especially in high-risk cases. To collect and determine the dosage of the IPF by PLT apheresis, a standardized procedure is essential. The next step in the refinement of this methodology is the integrated output, which comprises a value that indicates the blood volume of selected donors that must be processed to obtain the desired PLT number and IPF. It involves the creation of a registry of “dedicated” donors.
