Abstract: In this study, we have generated terahertz (THz) frequency by a novel design of microring resonators for medical applications. The dense wavelength-division multiplexing can be generated and obtained by using a Gaussian pulse propagating within a modified PANDA ring resonator and an add/drop filter system. Our results show that the THz frequency region can be obtained between 40–50 THz. This area of frequency provides a reliable frequency band for THz pulsed imaging.

Keywords: THz imaging, THz technology, MRRs, PANDA, add/drop filter

Introduction
Nonlinear terahertz (THz) radiation is the electromagnetic spectrum which ranges from 30 THz to 100 GHz. It covers the region away from microwaves via mid to beyond infrared. Formerly, bulky and expensive equipment such as free electron lasers or the alternative employment of thermal sources produced weak, incoherent radiation. THz radiation gives rise to rotational and vibrating excitation of some biological molecules. THz radiation has also been used in tissue with differentiating abilities.1 There is an increasing tendency towards THz technology for the next wave of noninvasive biomedical instruments.2,3 THz pulse has many properties that could encourage the use of THz pulsed imaging (TPI) as a medical imaging tool. Moreover, THz waves are useful for the analysis of histopathological diagnosis, without any staining process.4 Rayleigh scattering of electromagnetic radiation increases with the inverse of the wavelength to the fourth power. However, there is no ionization hazard for biological tissue.5 TPI is a new technique based on broadband pulses of electromagnetic radiation of THz frequencies.6,7 Contrast images can be obtained for different degrees of THz wave absorption for normal tissues, such as muscles, fatty tissue and cartilage, as well as cancer tissue. We can obtain THz images using a microring resonator (MRR) in a wide range of wavelengths.8,9 The THz pulse interacts with the sample in reflection or transmission modes. The modified pulse is recorded as a time-series. The spectra information from THz pulses has been used to distinguish different types of soft tissues, such as muscle, fat, and kidney tissues.10,11

Methodology and results
In order to achieve a wide band frequency carrier, we propose a novel system consisting of MRRs for many communication applications such as a wireless THz communication system and faster data transfer, which requires higher carrier frequencies.12
In this paper, we use MRRs made of InGaAsP/InP material to enhance the channels of the frequency band for implementation in medical imaging.\textsuperscript{13}

The transfer function of the system uses Gaussian beam, described by Equation 1.\textsuperscript{14}

\[ E_{in} = A_i \exp(i \omega_0 t) \]  

(1)

Here, \( A_i \) is the amplitude of the optical field and \( t \) is the time for phase shift with frequency shift of \( \omega_0 \). The optical outputs from the first and second ring resonators are given by Equations 2 and 3,\textsuperscript{15,16}

\[ E_{out1} = E_i \left( \frac{\sqrt{1 - \kappa_1^2}(1 - \gamma)}{1 - \sqrt{1 - \kappa_1^2}(1 - \gamma)} \exp((-\alpha L/2) - jK_1 L_1) \right) \]  

(2)

\[ E_{out2} = E_i \left( \frac{\sqrt{1 - \kappa_2^2}(1 - \gamma)}{1 - \sqrt{1 - \kappa_2^2}(1 - \gamma)} \exp((-\alpha L/2) - jK_2 L_2) \right) \]  

(3)

Here, \( \kappa \) is the coupling coefficient, and \( K \) represents the wave number in vacuum. \( \gamma \) is the fractional coupling intensity loss. \( L_1 \) and \( L_2 \) are circumferences of the first and second rings. \( \exp(-\alpha L/2) \) shows the roundtrip loss coefficient and \( \alpha \) is the waveguide loss. For the PANDA system, the output optical fields from right and left rings are expressed by Equations 4 and 5.

\[ E_R = E_i \exp((-\alpha L/8) - (jK_n L/4)) \left( \frac{\sqrt{1 - \gamma_n^2}(1 - \gamma_n^2)}{1 - \sqrt{1 - \gamma_n^2}(1 - \gamma_n^2)} \exp((-\alpha L_n/2) - jK_n L_n) \right) \]  

(4)

\[ E_L = E_i \exp((-\alpha L/8) - (jK_n L/4)) \left( \frac{\sqrt{1 - \gamma_n^2}(1 - \gamma_n^2)}{1 - \sqrt{1 - \gamma_n^2}(1 - \gamma_n^2)} \exp((-\alpha L_n/2) - jK_n L_n) \right) \]  

(5)

Here, \( E_R \) and \( E_L \) are the outputs from the right and left rings of the PANDA system. The interior output fields of \( E_1 \), \( E_2 \), \( E_3 \), and \( E_4 \) are expressed in Equations 6–9.

\[ E_1 = \frac{j \sqrt{1 - \gamma_n^2}}{1 - \sqrt{1 - \gamma_n^2}} \left( E_i - E_R E_i \right) \]  

(6)

\[ E_2 = E_R E_i \exp((-\alpha L/4) - (jK_n L/2)) \]  

(7)

\[ E_3 = E_i E_R \sqrt{(1 - \kappa_1^2)(1 - \gamma)} \exp((-\alpha L/4) - (jK_n L/2)) \]  

(8)

\[ E_4 = E_i E_R \sqrt{(1 - \kappa_1^2)(1 - \gamma)} \exp((-\alpha L/2) - jK_n L) \]  

(9)

Therefore, the final equations for drop port and throughput power are given in Equations 10–13.

\[ E_d = E_i \sqrt{(1 - \kappa_1^2)(1 - \gamma)} \]  

(10)

\[ + j \sqrt{1 - \kappa_3(1 - \gamma)} \]  

(11)

\[ \times E_R E_i \exp((-\alpha L/2) - jK_n L) \]

\[ P_t = (E_i) \cdot (E_i)^* = |E_i|^2 \]  

(12)

\[ P_d = (E_d) \cdot (E_d)^* = |E_d|^2 \]  

(13)

where \( P_t \) and \( P_d \) represent the output powers of the throughput and drop port, respectively.\textsuperscript{14,15}

In this work we use a Gaussian beam as an input power to the proposed system. The new design of the system is illustrated in Figure 1. In this case the Gaussian pulse with a center wavelength of 1.3 µm, pulse width of 20 ns, and power of 1 W, is an input into the system as shown in Figure 2A. The parameters used are \( R_f = 5 \) µm (radius of first ring), \( R_s = 3 \) µm (radius of second ring), \( R_s = 1 \) µm (radius of left ring of PANDA), \( R_s = 1 \) µm (radius of right ring of PANDA), \( R_s = 3 \) µm (radius of centered ring of PANDA), \( A_{off} = 0.10–0.25 \) µm.\textsuperscript{2} Some fixed parameters such as nonlinear refractive index, \( n_n = 3.34 \) (InGaAsP/InP)\textsuperscript{17} and intensity attenuation coefficient, \( \alpha = 0.2 \) dB/mm\textsuperscript{-1} have been selected for this system. The coupler intensity loss is \( \gamma = 0.1 \). The coupling coefficient of the MMR varies from 0.1–0.98. The nonlinear refractive index is \( n_n = 2.2 \times 10^{-17} \).

The input pulse is sliced to a smaller signal through the spectrum shown in Figure 2B and C. The light pulse can be chopped into discrete signals and amplified in the first ring, where more signal amplification is obtained by the second ring (smaller ring). The output signals from the
second ring resonator are inputs into the PANDA system. Output signals of the PANDA system are simulated and shown in Figure 3A–F. Figure 3E and F show the best region of frequency, which can be seen at the range of 40–50 THz. In practice, the channel frequency can be increased by using the system. Finally, the required signals can be obtained via the PANDA system.

The output signals from the PANDA system are inputs to the add/drop filter system in order to cancel out noisy chaotic signals. To retrieve the signals from the chaotic noise, we suggest the use of add/drop filters with proper parameters.

Two complementary optical circuits of the MRR add/drop filter can be illustrated by Equations 14 and 15.17

\[
\frac{|E_{1f}|^2}{|E_1|^2} = \frac{(1-\kappa_1^2) - 2\sqrt{1-\kappa_1^2} \cdot \sqrt{1-\kappa_2^2} \cdot e^{-\alpha L} \cos(kL) + (1-\kappa_2^2) e^{-\alpha L}}{1 + (1-\kappa_1^2)(1-\kappa_2^2) e^{-\alpha L} - 2\sqrt{1-\kappa_1^2} \cdot \sqrt{1-\kappa_2^2} e^{-\alpha L} \cos(kL)}
\]  

(14)

\[
\frac{|E_{1d}|^2}{|E_1|^2} = \frac{\kappa_1 \kappa_2 e^{-\alpha L}}{1 + (1-\kappa_1^2)(1-\kappa_2^2) e^{-\alpha L} - 2\sqrt{1-\kappa_1^2} \cdot \sqrt{1-\kappa_2^2} e^{-\alpha L} \cos(kL)}
\]

(15)

where $E_{t1}$ and $E_{t2}$ represent the optical fields of the throughput and drop port, respectively. $\beta = k n_{\text{eff}}$ is the propagation constant, $n_{\text{eff}}$ is the effective refractive index of the waveguide, $L = 2\pi R$ is the circumference of the ring, and $R$ is the radius of the ring. For simplification, we define the phase constant as $\phi = \beta L$. Chaotic noise cancellation and required signals can be obtained by using the particular parameters of the add/drop device. $\kappa_1$ and $\kappa_2$ are coupling coefficients of the add/drop filters, $\kappa = 2\pi \lambda$ is the wave propagation number for a vacuum, where the waveguide

loss is $\alpha = 0.2 \text{ dB/mm}$. The fractional coupler intensity loss is $\gamma = 0.1$. For the add/drop filter device, the nonlinear refractive index is neglected.

We used an add/drop filter system with a radius of 10 $\mu$m to determine the free spectral range, the number of channels and bandwidth as shown in Figure 4. Figure 5 shows the simulation results where Figure 5A and B represent the throughput and drop port outputs of the system, respectively.

As demonstrated in Figure 6, generated dense wavelength-division multiplexing from the proposed configuration of ring resonators are involved in the THz region, which provides a reliable frequency band for medical applications, especially for THz imaging. The main advantage of THz imaging is its diagnostic capabilities. These obtained pulses are also useful for analysis of the histopathological diagnosis, without any staining process.

To date, imaging spectroscopy is used only for small areas. THz imaging exactly reflects the tissue situation, for instance tumor, nontumor tissues, tissue degeneration, and fibrosis. The THz image shows significantly reduced absorption of THz radiation in this region compared with normal tissue, which suggests its usefulness for detecting tumors (Figure 7). Contrast images associated with different degrees of absorption of THz waves have been obtained for normal tissues, such as muscles, fatty tissue, and cartilage, as well as for cancer tissue. We could obtain THz images of large areas from an MRR in a wide range of wavelengths.
Conclusion
In this study, a new MRR design has been introduced, which provides the best frequency band when the input Gaussian pulse is used. This system consists of a series of MRRs connected to a PANDA system. Using the proposed system, multifrequency bands can be generated and simultaneously linked to an add/drop filter where it is suitable for analysis of the histopathological diagnosis. The results show the frequency band region lies between 40–50 THz. This range provides a reliable frequency band for medical purposes, especially in THz imaging.
