Abstract: Central retinal vein occlusion (CRVO) is frequent in patients with systemic lupus erythematosus (SLE), but the treatment of the macular edema with this disease is extremely difficult. We report a case of cystoid macular edema (CME) secondary to unilateral CRVO in a patient with SLE that responded to intravitreous injection of an anti-vascular endothelial growth factor (VEGF) agent. A 33-year-old Japanese woman was referred to our department with unilateral impairment of vision. Microperimetry (MP-1) showed a cessation of foveal sensitivity. Fluorescein angiography showed CME without ischaemia of the macular region or peripheral retina (nonischemic CRVO). A diagnosis of CME and unilateral nonischemic CRVO combined with SLE was made and intravitreous anti-VEGF therapy was given. A sample of aqueous humor was harvested at the start of intravitreous injection after obtaining informed consent. Then the levels of VEGF and monocyte chemotactic protein (MCP)-1 were measured in the aqueous humor by enzyme-linked immunosorbent assay, revealing that VEGF was 234 pg/mL and MCP-1 was 501 pg/mL. Two weeks later, left eye vision improved to 20/20. Optical coherence tomography (OCT) showed considerable amelioration of retinal swelling and CME. MP-1 showed a marked increase of foveal sensitivity. However, she had recurrence of edema 3 months later. After harvesting aqueous humor again, intravitreous injection of an anti-VEGF agent was repeated for CME. The aqueous VEGF and MCP-1 levels were 156 pg/mL and 360 pg/mL, respectively. These findings suggest that inflammation was improved by intravitreous injection of bevacizumab. Intravitreous injection of anti-VEGF agents may be effective for CME due to nonischemic CRVO in SLE patients if their inflammatory factor levels are low.

Introduction
Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder that affects multiple organs, including the eye. Ocular symptoms are usually due to retinal vascular manifestations of this disease, such as central retinal vein occlusion (CRVO), which is frequent in patients with SLE. We report an SLE patient with macular edema and unilateral CRVO who responded to intravitreous injection of an anti-vascular endothelial growth factor (VEGF) agent.
DNA antibody (anti-dsDNA). Antiphospholipid antibodies (both anticardiolipin and lupus anticoagulant) were negative. Serology for syphilis, human immunodeficiency virus 1 and 2, and hepatitis B and C was negative. Blood cultures showed no growth. Urinalysis was within normal limits. Magnetic resonance imaging of the central nervous system (CNS) revealed findings compatible with the diagnosis of CNS vasculitis.

Treatment of cystoid macular edema (CME) was started with intravitreous injection of an anti-VEGF agent (bevacizumab, 1.25 mg/0.05 mL). A sample of undiluted aqueous humor was harvested at the start of intravitreous anti-VEGF therapy after informed consent was obtained following an explanation of the purpose and potential adverse effects of the procedure. This study was performed in accordance with the Helsinki Declaration of 2008 (sixth revision), and our institutional review board of Tokyo Women’s Medical University also approved the protocol for collection of aqueous humor. The levels of VEGF and monocyte chemotactic protein-1 (MCP-1) were measured in the aqueous humor sample by using enzyme-linked immunosorbent assay kits for human VEGF and MCP-1 (R&D Systems, Minneapolis, MN, USA).3 As a result, the VEGF level was 234 pg/mL and the MCP-1 level was 501 pg/mL.

Case report
A 33-year-old Japanese woman was referred to our department with unilateral impairment of vision. Six months earlier, SLE was diagnosed on the basis of a malar rash, polyarthritis, leukopenia, and elevation of ANA and anti-dsDNA antibody.1 At the initial examination, visual acuity (VA) was 20/100 in the left eye. Superficial and deep intraretinal hemorrhages were scattered throughout the retina, suggesting that the patient had CRVO (Figure 1A). Fluorescein angiography showed CME without ischemia of the macula or the peripheral retina (Figure 1B). Optical coherence tomography (OCT) identified retinal swelling and CME (Figure 1C). Fundus-monitored microperimetry with the MP-1 system (D) indicates a cessation of foveal sensitivity.

Two weeks later, VA of the left eye had improved to 20/20. OCT showed marked alleviation of retinal swelling and CME at 2 weeks after the first intravitreous injection of bevacizumab. OCT (B) reveals the recurrence of macular edema at 3 months after intravitreous anti-vascular endothelial growth factor (VEGF) therapy. OCT (C) displays marked improvement of retinal swelling and CME at 1 week after the second intravitreous injection of bevacizumab. Fundus-monitored microperimetry with the MP-1 system (D) demonstrates improvement of foveal sensitivity.

Discussion
Retinal vascular changes are frequent in patients with SLE.2 The classic retinal findings are hemorrhages and cotton
wool spots and VA is generally unaffected. If macular edema occurs, however, it leads to visual impairment. In the present patient, visual acuity, retinal sensitivity, and macular edema were all improved by two intravitreous injections of an anti-VEGF agent (bevacizumab). VEGF decreased from 234 to 156 pg/mL after the first injection and MCP-1 also decreased from 501 to 360 pg/mL. This finding is supported by the report that changes of VEGF after intravitreous anti-VEGF therapy significantly associated with changes of MCP-1, and it suggests that inflammation was improved by intravitreous injection of bevacizumab. It has been reported that anti-VEGF treatment is more effective for nonischemic CRVO than ischemic CRVO, and we previously reported that aqueous VEGF levels are significantly higher in patients with ischemia than in those without ischemia. The present patient had nonischemic CRVO with relatively low levels of VEGF (234 pg/mL and 156 pg/mL), which means that she was more likely to respond to intravitreous anti-VEGF therapy.

**Conclusion**

These findings suggest that inflammation was improved by intravitreous injection of bevacizumab. Intravitreous anti-VEGF therapy may be effective for CME due to nonischemic CRVO in SLE patients with low levels of inflammatory factors.
