**Background:** Nontyphoidal *Salmonella* (NTS) species are important food-borne pathogens that cause gastroenteritis and bacteremia, and are responsible for a huge global burden of morbidity and mortality. The aim of this study was to investigate the prevalent serogroups and antibiotic resistance of NTS in our region.

**Methods:** We reviewed the serogroup distribution and antimicrobial susceptibility patterns of NTS strains obtained from 158 stool specimens of patients with acute diarrheal infection attending the outpatient and inpatient department at a university hospital in the Eastern Province of Saudi Arabia in the period from September, 2008 to April, 2011. A retrospective analysis of the 158 patients with NTS infection was conducted to determine the most prevalent NTS serogroups causing acute gastroenteritis and their antimicrobial susceptibility patterns.

**Results:** At this teaching hospital, a total of 17,436 fecal samples were analyzed during the 2008–2011 study period. Of these specimens, 158 tested positive for NTS, giving an overall prevalence of 9.06 per 1,000. Of 158 NTS cases, serogroup D1 (25.3%) was the most prevalent, followed by serogroup B (19.6%), and serogroup C1 (18.9%). One third of all NTS serogroup strains tested were resistant to tetracycline. The NTS strains showed resistance to ampicillin (31.3%), amoxicillin/clavulanic acid (29.9%), trimethoprim/sulfamethoxazole (20.9%), and cefotaxime (14.93%).

**Conclusion:** The findings of this study support the concern that use of antibiotics in animal feeds may contribute to acquisition of resistance in food-borne bacteria, such as *Salmonella*. Our study also concludes that the prevalence of NTS in the Eastern Province of Saudi Arabia is very low compared with other studies worldwide.

**Keywords:** nontyphoidal *Salmonella*, serogroups, prevalence, antimicrobial resistance, Saudi Arabia

**Introduction**

*Salmonella* are motile Gram-negative facultative anaerobic bacteria in the family Enterobacteriaceae. The *Salmonella* genus consists of two species, ie, *Salmonella enterica* and *Salmonella bongori*.¹ Most pathogenic species of *Salmonella* causing illness in humans belong to the *S. enterica* species.² This species is further divided into six subspecies, ie, *S. enterica* subspecies enterica, *S. enterica* subspecies salamae, *S. enterica* subspecies arizonae, *S. enterica* subspecies diarizonae, *S. enterica* subspecies houtenae, and *S. enterica* subspecies indica. Nontyphoidal salmonellosis is caused by *Salmonella* species other than *Salmonella typhi* and *Salmonella paratyphi*. Nontyphoidal salmonellosis
is one of the leading food-borne illnesses and accounts for considerable morbidity and mortality in both developed and developing countries. For instance, in the US, it was estimated that nontyphoidal salmonellosis accounted for 11% (rank number two) of food-borne illnesses, 35% (rank number one) of food borne-associated hospitalization, and 28% (rank number one) of foodborne-associated death.³,⁴

Nontyphoidal Salmonella (NTS) is recognized as one of the principal causes of food-borne infections worldwide.⁵ Among the more than 2,000 Salmonella serovars, Enteritidis is one of the top serovars reported in Saudi Arabia.⁶ Most cases of gastroenteritis caused by serovar Enteritidis occur sporadically or as limited outbreaks, but recent reports of large hospital-associated and nursing home-associated outbreaks emphasize the importance of serovar Enteritidis infection as a major public health problem.⁵,⁷,⁸ NTS is an important bacterial cause of diarrhea and community-acquired bloodstream infection.⁹,¹⁰ Globally, NTS gastroenteritis is estimated to cause 93.8 million illnesses and 155,000 deaths each year.¹¹ Invasive NTS infection occurs when the organism spreads beyond the gastrointestinal mucosa to infect normally sterile sites, such as the bloodstream, meninges, bone, and joint spaces.¹²

Identification of NTS in fecal samples from patients is the first step in treating patients. Usually, the first line of treatment used by physicians is antibiotics. However, misuse of antibiotics inevitably leads to antibiotic resistance. The US Centers for Disease Control have discovered that, since the 1990s, NTS has shown increasing resistance to antibiotics, including ampicillin and chloramphenicol.¹³ Therefore, initial studies on NTS should not be restricted to prevalence, but should also include their antibiotic resistance. In the light of the above, the aim of the present study was to determine the prevalence and antimicrobial susceptibility of NTS serogroups at King Fahd Hospital of the University (KFHU), Al-Khobar, Saudi Arabia.

**Materials and methods**

**Study design**
Clinical records of Salmonella strains from the clinical microbiology laboratory at KFHU for the period September 2008 to April 2011 were retrospectively reviewed. The KFHU routinely collects fecal samples from all patients admitted with acute gastroenteritis and diarrheal illness.

**Culture procedure**
All fecal samples were cultured directly on Hektoen agar and xylose lysine deoxycholate agar, inoculated in selenite F broth (Oxoid Ltd, Basingstoke, UK), subcultured, and identified further using an automated card system (bioMérieux Vitek Inc, Hazelwood, MO, USA) and the API 20E (bioMérieux, Marcy l’Etoile, France). All isolates were identified as Salmonella according to standard microbiologic techniques.¹³ The identified Salmonella isolates were then serogrouped using somatic group Salmonella A–G antisera (Murex Biotech Ltd, Dartford, UK).

**Antibiotic susceptibility testing**
Antibiotic susceptibility testing was determined using an automated Vitek machine with Gram-negative bacteria cards, which gave minimum inhibitory concentration results and interpretation of the results as resistant or susceptible according to the breakpoints for each antibiotic. Some antibiotic susceptibility testing was determined by means of the Kirby-Bauer disk diffusion method using the guidelines provided by the Clinical Laboratory Standards Institute (CLSI), formerly known as the National Committee for Clinical Laboratory Standards.¹⁴ Susceptibility tests were done on Mueller Hinton agar (Oxoid Ltd) using the following concentrations (µg/disc) of antibiotics (Oxoid Ltd): ampicillin 10 µg, amoxicillin/clavulanic acid 20/10 µg, amikacin 30 µg, aztreonam 30 µg, cefotaxime 5 µg, ceftriaxone 30 µg, cefalothin 30 µg, ciprofloxacin 5 µg, gentamicin 10 µg, imipenem 10 µg, piperacillin 100 µg, and trimethoprim/sulfamethoxazole (1.25 µg/23.75 µg). Results were scored as susceptible, moderately susceptible, or resistant, according to CLSI criteria. Escherichia coli 25922 (American Type Culture Collection, Manassas, VA, USA) was used as the reference strain.

**Statistical analysis**
The data were analyzed using bivariate tables and scatter graphs. The change in distribution over the years was analyzed using the chi-square test for a trend in situations where it is applicable (zeros not being adjacent to each other or cell frequencies not being less than two). The similarity of the distribution of the serogroups across the different years was tested using the Kruskal–Wallis test. The chi-square goodness of fit test was used to assess how a distribution compared with uniform distribution. For all tests, a P-value <0.05 was considered to be statistically significant. Analysis was done using MS Excel 2007 (Microsoft, Redmond, WA, USA) and PAST statistical software (version 2.04).¹⁵

**Results**
At this teaching hospital, a total of 17,436 fecal samples were analyzed during the 2008–2011 study period. Of these specimens, a total of 158 tested positive for NTS, giving an
overall prevalence of 9.06 per 1,000. The figures for each year are shown in Table 1. As can be seen, the prevalence increased from 7.0 per 1,000 in 2008 to 9.89 per 1,000 in 2009; thereafter, the prevalence declined slightly between 2009 and 2011. Positive NTS samples during 2009 and 2010 remained constant at between 40 and 41 of total positive samples, but the trend varied among the different serogroups. Serogroup D remained the most frequent of the *Salmonella* serogroups. The annual prevalence of serogroup D increased by more than half in 2011 compared with 2008 (Table 2).

From 2008 to 2011, 158 strains of NTS were isolated from fecal samples of patients with gastroenteritis. *Salmonella* strains belonging to serogroup D1 had the highest prevalence (25.3%) followed by serogroup B (19.6%), and C1 serogroup (19%). *Salmonella* serogroup strains belonging to F (0.6%), G1 (1.3%), and H (1.3%) were the least prevalent (Table 2). The distribution of serogroups is shown in Figure 1. The only serogroup showing a clear increase in trend is D1. The chi-square test for trend confirms that the only significant change in slope over the study period occurred in serogroup D1. The trend for D1 is fairly linear. The Kruskal–Wallis test does not show any significant difference in year-to-year distribution between the different serogroups (Table 2). The distribution of serogroups is shown in Figure 1. The only serogroup showing a clear increase in trend is D1. The chi-square test for trend confirms that the only significant change in slope over the study period occurred in serogroup D1. The trend for D1 is fairly linear. The Kruskal–Wallis test does not show any significant difference in year-to-year distribution between the different serogroups (Table 2).

Resistance to ampicillin (31.3%) and amoxicillin/clavulanic acid (29.9%) was observed in most NTS strains. Resistance to sulfamethoxazole, trimethoprim, and cefotaxime was observed in 20.9% and 14.93% of strains (Table 3). Of all strains, the lowest resistance was noted with ciprofloxacin (3.0%, Table 3). The Kruskal–Wallis test did not show any significant difference in year-to-year distribution between the different antibiotics ($H=1.803$, $P=0.6205$). All strains were susceptible to amikacin, aztreonam, ceftriaxone, cephalothin, gentamicin, imipenem, and pipercillin.

Overall, antibiotic resistance in the NTS serogroup strains increased from 29.1% in 2008 to 32.1% in 2011. According to the chi-square goodness-of-fit test, this increase was not significantly different from the uniform distribution during the study period ($P=0.065$). Resistance to cefotaxime increased from 10.3% of all isolates in 2008 to 14.93% of all isolates in 2011 (Figure 2). The number of isolates showing resistance to trimethoprim/sulfamethoxazole fluctuated between six and eight throughout the study period. There was an increase in the number of isolates showing resistance to trimethoprim/sulfamethoxazole from four in 2008 to 16 in 2011 (Table 3). The highest overall resistance (40.2%) was observed among strains belonging to serogroup B, followed by serogroups C2 (18.6%), C1 and D1 (10.4%), and C3 (8.2%, Table 4).

### Discussion

NTS infections are a leading cause of food poisoning and enteric infection, and are an important public health problem worldwide. 

*Salmonella* may cause gastroenteritis in people of all ages, and is responsible for severe invasive disease in infants, the elderly, and the immunocompromised. The frequency of antimicrobial resistance and number of resistance determinants in *Salmonella* has risen markedly. 

Antimicrobial susceptibility to ampicillin, trimethoprim/sulfamethoxazole, and quinolones for *Salmonella* isolated from fecal specimens should be routinely tested and reported using the CLSI guidelines.

**Notes:** *chi-square trend test not applicable; total might be different from 100 because of rounding up.*
A surveillance study by Su et al demonstrated an obvious increase in overall antimicrobial resistance among *Salmonella* from 20%–30% in the early 1990s to as high as 70% in some countries at the turn of the century. Conventional antibiotics, such as ampicillin, chloramphenicol, and trimethoprim/sulfamethoxazole, are no longer an appropriate choice for the treatment of invasive salmonellosis. Increasing antimicrobial resistance in NTS is a global public health problem that complicates antimicrobial therapy, and is increasingly due to the overuse and misuse of antimicrobial agents in animal feeds. Several studies worldwide have reported increased morbidity and mortality in patients infected with resistant *Salmonella* strains. Resistance to antibiotics is posing a serious problem in the treatment of salmonellosis. In the present study, serogroup D1 (25.3%) was the most frequent and prevalent serogroup, followed by serogroup B (19.6%) and serogroup C1 (18.9%). There was an increase in gastroenteritis caused by serogroup D1 from 2008 to 2011 (Figure 1 and Table 2).

Our study also confirms the emergence and rapid increase in cases of NTS infection with serogroup D1, particularly serovar Enteritidis. A similar study conducted by Chiu et al at a university hospital in Taiwan reported that the incidence of serogroup D *Salmonella* has been increasing in Taiwan. The present study indicates that serogroup D was more prevalent than serogroup B and other serogroups, and if this trend were to continue, the incidence of NTS serogroup D would soon surpass that of serogroup B infection. Such a trend has been reported in the US, Europe, Taiwan, Malawi, Thailand, and Malaysia. Serovar Enteritidis is known to be closely associated with layer and broiler flocks, and infection is generally believed to be derived from poultry and poultry products, including eggs.

The current study findings are consistent with those of other studies reporting that most of the NTS (serovar Enteritidis) are resistant to a wide range of antimicrobial agents. However, in our study, we found a higher rate of resistance to trimethoprim/sulfamethoxazole (17.7% of

isolates during the period from September, 2008 to April, 2011, Table 3). These findings are in agreement with those of a similar study on the emergence of *Salmonella* with extended spectrum β-lactamase enzymes that hydrolyze and confer resistance to cefotaxime in several European countries. In the present study, some of the strains (14.93%) were reported to be resistant to cefotaxime and ciprofloxacin (3%). Ciprofloxacin and cefotaxime are the antimicrobial agents recommended for treatment of invasive infections due to *Salmonella*.

NTS species are important food-borne pathogens, with acute gastroenteritis being the most common clinical manifestation. However, invasion beyond the gastrointestinal tract occurs in approximately 5% of patients with NTS gastroenteritis, resulting in bacteremia. In industrialized countries, NTS constitutes a well recognized public health problem that, in healthy subjects, is usually encountered clinically as self-limited gastroenteritis. In immunocompromised and debilitated hosts, NTS can become invasive, leading to bacteremia, sepsis, and focal infections (eg, meningitis). Invasiveness is also observed in infants younger than 3 months of age who become infected with NTS in industrialized countries, resulting in bacteremia and focal infections.

We conclude that there is a need to establish standard first-line therapy for salmonellosis. Clinicians should be aware of the local epidemiology of NTS and carefully review the results of antimicrobial susceptibility testing once available from the clinical laboratory. Active monitoring of NTS serogroups for antibiotic resistance patterns is essential because of potential acquisition of resistance genes by pre-existing serovar Enteritidis strains via horizontal gene transfer. Knowledge of the distribution of prevalence of *Salmonella* serogroups is potentially of epidemiologic and public health importance.
