Autopsy-certified maternal mortality at Ile-Ife, Nigeria

Aim: Maternal mortality is a major health problem, especially in Nigeria, where accurate autopsy-based data on the prevalent causes are not readily available. The aim of this study was therefore to accurately determine the causes of maternal death as seen in a tertiary health facility in Nigeria.

Materials and methods: This was a descriptive, retrospective review of the postmortem autopsy findings from cases of maternal death at the Obafemi Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria over a 5-year period. Analyses were performed for differences in proportions using PEPI computer programs for epidemiologists (P is significant at ≤0.05).

Results: A total of 84 cases of maternal deaths were used for the study. Approximately 71.4% of the maternal deaths were due to direct causes and 28.6% were due to indirect causes. The mean age at the time of death was 27.9 ± 7.5 years. Overall, the three leading causes of death were obstetric hemorrhage (30.9%), complications of abortion (23.8%), and nongenital (nonobstetric) infections (14.2%). Of the direct causes of maternal death, obstetric hemorrhage (43.3%) was the leading cause, with postpartum hemorrhage accounting for most (65.0%) of such deaths; other causes included complications of unsafe induced abortion (33.3%) and of labor (11.7%). Of the indirect causes, nongenital infections (50.0%), anemia (25.0%), and preexisting hypertension (20.8%) accounted for the majority of the maternal deaths. There was disparity between the clinical and autopsy diagnoses in 34 of the 84 cases (38.1%).

Conclusion: The leading causes of maternal death in this study are similar to those in other developing countries. Autopsy is an invaluable tool in accurately determining the cause of maternal death.

Keywords: autopsy, causes, maternal mortality, Nigeria

Introduction

Approximately 250,000 African women are said to die yearly during pregnancy, delivery, or the puerperium. Maternal deaths in Nigeria contribute significantly to this number. In fact, data from the United Nations and the World Bank have identified Nigeria as one of the worst places in the world for a woman to give birth, with about 59,000 women dying every year due to pregnancy-related complications. The average maternal mortality rate in Nigeria is estimated to be about 704 deaths per 100,000 live births, although this number ranges from about 165 deaths per 100,000 live births in the southwest region to 1,549 deaths per 100,000 live births in the northeastern subregions of the country. These unacceptably high rates have prompted the Nigerian government to join the international community in adopting...
the Millennium Development Goal of reducing maternal
mortality rate by 75% by the year 2015. Although many
policies and programs have been put in place over the years
to achieve this goal, the results have been less than optimal,
possibly because they have been driven by limited scientific
information, most of which has been obtained from clinical
records and verbal autopsies.3–5

The role of the autopsy as a tool in the prevention and
reduction of maternal deaths has been well-documented,
especially in developed countries where maternal mortal-
ity rates are now so low that perinatal death rates are more
appropriately used as an index of the state of the health
system. In such countries, thorough postmortem examina-
tions are regularly conducted as part of confidential inquiries
into maternal deaths, with reports being published at regular
intervals.6

Information provided by medical autopsies is known
to increase the accuracy of cause of death reports, even in
cases where the cause of death can be wholly based on clin-
ical evaluation.7–10 Maternal autopsies are thus required for
accurate death certification, determination of the underlying
causes of death, and establishment of maternal mortality
rates.5 These are invaluable tools for reducing and prevent-
ing maternal deaths.

In accordance with recommendations from the Safe
Motherhood Conference held in Abuja in 1990, the Federal
Government of Nigeria has directed that confidential inqui-
ries be conducted for maternal deaths in Nigeria (with the
autopsy as a pivotal tool) and that regular reports be made to
the Federal Ministry of Health.5 This has led to an increase in
the demand for maternal autopsies at the Obafemi Awolowo
University Teaching Hospitals Complex, Ile-Ife, Nigeria
(OAUTHC), a referral tertiary health care facility located
in the southwestern region of Nigeria.

The aim of this study was to review the autopsy find-
ings from postmortem examinations conducted on cases of
maternal mortality at the OAUTHC tertiary health facility,
in order to accurately determine the causes of maternal death prevalent in our environment.

Materials and methods

This was a descriptive retrospective study of the autopsy
findings from postmortem examinations conducted on cases
of maternal mortality in the Department of Morbid Anatomy
and Forensic Medicine, OAUTHC, between January 1, 2005
and December 31, 2009. The cases selected for the study
were those that satisfied the World Health Organization de-

The patients were also grouped into different parity
groups: never given birth (Nullipara); given birth one time
(Para 1); given birth two, three, or four times (Para 2–4); given
birth more than four times (>Para 4). These parity groups
were compared with the various causes of maternal death.

The data obtained was analyzed using Computer Pro-
grams for Epidemiologists (PEPI).12 Univariate analysis was
carried out and the causes of maternal deaths were presented
in frequencies and percentages. Chi-square analysis was
 performed with the P-value set at 0.05.

Ethical approval for this study was obtained from the
OAUTHC Ethics and Research Committee.

Results

During the 5-year period under review, a total of 1,969 autop-
sies were performed in the OAUTHC Department of Morbid
Anatomy and Forensic Medicine. A total of 128 maternal
deaths occurred during 7,472 live births during this period,
resulting in a maternal mortality rate of 1.713 per 100,000
live births. Autopsies were conducted on 102 (5.2%) of all
In an examination of maternal deaths by pregnancy stage, most (57.1%) causes of maternal death occurred during the third trimester, delivery, and puerperium (Table 2). Second-trimester deaths (29.8%) were mainly due to complications of abortion, nongenital infections, obstetric hemorrhage, and anemia. A statistically significant relationship was found between the timing of pregnancy and direct causes of maternal death ($P<0.001$). Overall, 33.3% of maternal deaths were due to infectious diseases (puerperal sepsis, postabortion sepsis, and nongenital infections).

Among the 26 cases of obstetric hemorrhage, 17 (65.4%) occurred postpartum and nine (34.6%) occurred antepartum (Table 3). About 66.7% of antepartum hemorrhages were due to abruptio placentae. On the other hand, about 76.4% of postpartum hemorrhages were due to uterine atony. Uterine atony occurred only in Nullipara (15.4%) and Para 3 (86.6%) women. Other causes were ruptured or perforated uterus (11.8%) and retained placenta (11.8%). Of the seven cases arising from complications of labor, five (71.4%) were due to puerperal sepsis and two (28.6%) were due to aspiration pneumonitis. Complications of abortion were predominantly due to postabortion sepsis (55.0%), severe hemorrhage (25.0%), and uterine perforation (20.0%). All deaths from complications of abortion occurred in the first (45.0%) and second (55.0%) trimesters of pregnancy (Table 2). According to Figure 1, obstetric hemorrhage and complications of labor were more common among Para 2–4 individuals, whereas the complications of abortion and preeclampsia/eclampsia were more common in Nullipara women. These observations were found to be statistically significant ($P<0.009$).

Anemia in pregnancy was mainly nutritional, with only one case due to sickle-cell disease. Death resulted from anemic heart failure in all of these cases. Deaths due to nongenital infections were bacterial in origin and included pyogenic meningitis (41.7%), pulmonary tuberculosis (25.0%), pneumonia (25.0%), and tuberculous meningitis (8.3%). Deaths resulting from the complications of preexisting essential hypertension were due to malignant hypertension (40.0%), left ventricular failure (40.0%), and intracranial hemorrhage (20.0%).

There was disparity between the clinical and autopsy diagnoses in 34 of the 84 cases (38.1%). In such cases, the final autopsy diagnoses were nongenital infections (23.5%),

Notes: A statistically significant relationship was found between the timing of pregnancy and direct causes of maternal death (P<0.001). The relationship between pregnancy and indirect causes of maternal death was not significant (P>0.05).

Abbreviations: T1, first trimester; T2, second trimester; T3, third trimester.

Discussion

Direct (obstetric) causes accounted for the vast majority (71.4%) of maternal deaths in this autopsy-based study, with obstetric hemorrhage accounting for a significant number of cases. In fact, obstetric hemorrhage was the single most frequent cause of maternal death overall. Also worthy of note is the fact that most postpartum hemorrhages were due to uterine atony, especially in high-risk women who belonged to the high-parity group. These women were also more likely to be in the older age groups. These findings are in agreement with various studies conducted in other parts of Nigeria and in other developing countries.1,10,11-16 These facts reflect the poor state of the health care delivery system prevalent in these regions. It is therefore vital that improved management of the later stages of pregnancy, delivery, and postpartum period that takes into account well-defined risk factors and provides improved facilities to correctly treat these complications be made available, especially at the primary care level. This is pertinent because most cases of maternal deaths in the tertiary care centers in Nigeria are those referred from various poorly equipped primary care centers.2 Interestingly, the frequencies of puerperal sepsis and preeclampsia/eclampsia were quite low when compared with the other causes of obstetric deaths.

Also noteworthy is the high proportion (23.8%) of complications resulting from unsafe induced abortion. Complications of unsafe abortion remain a major cause of maternal mortality in developing countries, due to the fact that abortion is illegal in most of such countries, including Nigeria. The types of complications arising from these unsafe (and illegal) abortions (septicemia, severe hemorrhage, uterine perforation) suggest that these procedures were performed either by unqualified personnel or carried out in inappropriate care centers. This is buttressed by the fact that most of the affected women in this study were young (<25 years of age) and unmarried dependents.17,18

Overall, the results of this study suggest that infectious diseases contribute significantly to maternal mortality, constituting 33.3% of cases. A significant proportion of these were due to infections not directly related to the pregnancy (nongenital infections). These nongenital infections accounted for 50.0% of all obstetric or indirect maternal deaths (and 14.2% of all maternal deaths) and included easily

</table>
treatable conditions, some of which are typically associated with low case-fatality rates. The prompt diagnosis and treatment of infectious diseases during pregnancy may thus have a significant impact on reducing maternal mortality in this environment.

Direct or obstetric causes of maternal deaths, unlike the indirect causes, are well-known to be associated with increasing maternal age, parity, and the stage of the pregnancy, as these factors have direct physiological effects on the outcomes of the pregnancies. These facts were corroborated by this study, which showed that complications from unsafe abortions and pregnancy-induced hypertension were more common in the younger age group, whereas obstetric hemorrhages were more common in women older than 25 years of age and in the third trimester. Although complications from unsafe abortions and ectopic pregnancy were more common in the first and second trimesters, complications associated with pregnancy-induced hypertension were more likely in the later stages of pregnancy.

Poverty and poor education are well-known to contribute significantly to maternal mortality. In this study, 70.0% of maternal deaths occurred among the unskilled, unemployed, and student populations. This may explain why many of these women did not receive any proper form of antenatal care, the lack of which is well-known to contribute significantly to maternal mortality. Our study showed that 67.0% of the women did not receive antenatal care and were seen for the first time when they presented with various complications.

In the developing world, where maternal mortality rates are highest, the leading causes of death are well-known. Nevertheless, complex disease processes with uncertain pathogenesis and clinical presentations can pose a problem for accurate death certification, even in developed countries. These may adversely affect the accuracy of the relevant data on maternal mortality, with the attendant consequences on efforts geared at reducing it. Thus, maternal autopsies are required for accurate death certification and determination of the actual underlying causes of death. Our study showed discrepancies between the clinical and autopsy-based diagnoses in 38.1% of cases. These discrepancies cut across all of the various causes of maternal death. This greatly underscores the importance of maternal autopsies in making accurate diagnoses with the attendant consequences for the prevention and reduction of maternal deaths, which have been well-documented in many developed countries.

The maternal mortality rate observed in this study (1,713 deaths per 100,000 live births) is much higher than the Nigerian national average, which ranges between 165 deaths per 100,000 live births in the southwest region.
to 1,549 deaths per 100,000 live births in the northeastern subregions of the country. Similarly, results from this study may not accurately reflect the entire community, because the study center (OAUTHC) is at the highest referral level for the country. Nevertheless, this study underscores the poor state of Nigeria’s health care delivery system. Efforts should therefore be mobilized to ensure great improvement in the nearest future.

Acknowledgments

We wish to acknowledge the input of Professor Olusegun Fatasi on the statistical aspect of the work and the staff members of the Department of Morbid Anatomy and Forensic Medicine, Obafemi Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria for their encouragement and cooperation during the study.
