Abstract: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have been demonstrated to improve responses and clinical outcomes significantly in patients with advanced non-small-cell lung cancer (NSCLC). In retrospective subgroup analyses of several studies, patients with Asian ethnicity (including Chinese) are a subpopulation who responds well to EGFR TKI therapy. Since EGFR-mutation status has emerged as an important predictor of a substantially increased benefit, the high mutation rate in the Asian (including Chinese) population could be the explanation for a superior benefit from EGFR TKI therapy. Erlotinib (Tarceva®), one of the EGFR TKIs, has been proved to be effective in second- and third-line therapy, and furthermore in first-line and maintenance settings. In this review, we summarize current data of clinical trials with erlotinib and discuss its role in the targeted treatment of NSCLC in Chinese patients.

Keywords: NSCLC, EGFR TKI, erlotinib

Introduction

Lung cancer is the leading cause of cancer-related mortality in men and women throughout the world, including the People’s Republic of China (PRC).1,2 According to the Chinese Cancer Registry Annual Report, the crude incidence rate of lung cancer was 53.57 per 100,000 in 2009, and the incidence rate of males (70.40 per 100,000) was 1.94 times as much as that of female (36.34 per 100,000). The mortality rate of lung cancer was 45.57 per 100,000, and the mortality rate of male was (61.00 per 100,000), 1.94 times as much as that of females (29.77 per 100,000).1 In the last three decades, the morbidity and mortality rates of lung cancer in Chinese populations have increased annually and have become higher than the worldwide average, owing to growing smoking habits and environmental pollution.3

Non-small-cell lung cancer (NSCLC) comprises the most common form of lung cancer, with the majority of patients presenting with advanced disease at the time of diagnosis.4 For these patients, palliative chemotherapy with platinum-based doublets was once considered to be the only standard treatment, with limited efficacy and usually serious side effects.5,6 However, recent advances in targeted and individualized therapy have provided us with alternative approaches for the treatment of NSCLC. Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs), the most commonly studied targeted agents, have been demonstrated to improve responses and outcomes in patients with advanced NSCLC significantly.7 Erlotinib (Tarceva®; San Francisco, CA, USA), one of the oral EGFR TKIs, has been proved to be effective in second-and third-line therapy,8,9 and furthermore in first-line10–12 and maintenance settings.13

Therefore, erlotinib has been approved in more than 80 countries for the treatment of advanced NSCLC, and was also approved in the PRC in 2006.

In retrospective subgroup analyses of several studies, patients with Asian ethnicity are a subpopulation that responds well to EGFR TKI therapy.\textsuperscript{14,15} With further research focusing on identifying biomarkers to predict clinical benefit of EGFR TKIs, EGFR-mutation status has emerged as the strongest predictor for clinical benefit from EGFR TKI therapy.\textsuperscript{16,17} Therefore, the main reason for better outcomes in Asian patients compared with Western patients is probably the result of the higher incidence (around 30\textendash{}40\%) of EGFR-sensitive mutations in exon 19 and 21 in Asian patients than in Western patients.\textsuperscript{18–20} Not surprisingly, Chinese advanced NSCLC patients with a mutation rate of 49.8\% obtained significant benefit from EGFR TKI treatment.\textsuperscript{21}

In this review, we summarize current data of clinical trials with erlotinib and discuss its role in the targeted treatment of NSCLC in Chinese patients.

**Erlotinib as second-line or later therapy**

Several clinical trials have confirmed the antitumor activity of erlotinib as second-line or later therapy in patients with advanced NSCLC (Table 1). In the BR.21 study, a randomized, double-blind, Phase III trial in 731 patients with advanced NSCLC who had received at least one line of chemotherapy,\textsuperscript{8} erlotinib significantly prolonged survival: progression-free survival (PFS) 2.2 months versus 1.8 months (hazard ratio [HR] 0.61, \textit{P}<0.001; overall survival [OS] 6.7 months versus 4.7 months, HR 0.70, \textit{P}<0.001), delayed symptom deterioration, and provided quality of life benefits compared with placebo. The subgroup analysis showed that erlotinib was associated with longer survival among women (HR 0.70, \textit{P}<0.001), lifetime nonsmokers (HR 0.70, \textit{P}<0.001), and patients with adenocarcinoma (HR 0.70, \textit{P}<0.001). Based on these promising data, erlotinib was approved as standard treatment for advanced NSCLC in second- or third-line settings by the US Food and Drug Administration and the European Medicines Agency.

The Tarceva Lung Cancer Survival Treatment (TRUST) study was a large international, open-label, Phase IV study of erlotinib that was designed to investigate the efficacy of erlotinib monotherapy for patients with advanced NSCLC who had previously failed on or were considered unsuitable to receive standard chemotherapy.\textsuperscript{9,22} A total of 6,665 patients were enrolled into the study, with 1,242 patients recruited within the East/Southeast (E/SE) Asian region (including 519 patients in the PRC). To validate the hypothesis that treatment outcomes in the Asian population would be superior to the non-Asian population, further efficacy and safety data of erlotinib in E/SE Asian patients with advanced NSCLC were analysed.\textsuperscript{23} Compared with patients in other regions, both the overall response rate (ORR) and disease-control rate (DCR) were significantly higher in E/SE Asian patients (ORR 27\% versus 10\%, \textit{P}<0.0001; DCR 78\% versus 66\%, \textit{P}<0.0001; respectively). The median PFS for the E/SE Asian population was 5.78 months, compared with 2.92 months for the non-E/SE Asian population and 3.25 months for the overall global population. The median OS values were 14.7, 6.8, and 7.9 months, respectively. Multivariate analyses for PFS

and OS showed that smoking status (nonsmoker), histology (adenocarcinoma/bronchioloalveolar carcinoma), and sex (females) were all predictive of longer survival with erlotinib, while these characteristics were considered to be potentially indicative of a high incidence of EGFR mutation.29

As a subgroup of Asian patients, 519 Chinese patients were enrolled. Of these patients, one case had complete response, 127 cases had partial response, 263 cases had stable disease, and 88 cases had progressive disease, resulting in an ORR of 26.7%. The median time to progression (TTP) was 6.44 months, and median OS was 15.37 months. The major erlotinib treatment-related adverse events (AEs) were mild (Common Terminology Criteria AE grade 1/2), while only three cases had severe AEs and one case had interstitial lung disease and died of respiratory failure.

To investigate the role of erlotinib further as second-line treatment in unselected advanced NSCLC patients, the Docetaxel and Erlotinib Lung Cancer Trial (DELTA) study was conducted to compare the efficacy of erlotinib with docetaxel in patients previously treated with chemotherapy.24 The primary analyses focusing on EGFR wild-type tumors were reported at the annual meeting of the American Society of Clinical Oncology (ASCO) 2013, and revealed that patients with EGFR wild-type tumors achieved significantly longer PFS in the docetaxel arm than in the erlotinib arm (median PFS 2.9 months versus 1.3 months, P=0.013), while the difference did not translate into OS (median OS 9.0 months versus 9.2 months, P=0.914). Another Phase II trial, Chinese Thoracic Oncology Group (CTONG) 0806, which was also reported at the ASCO 2013 meeting, compared pemetrexed with gefitinib as second-line treatment of nonsquamous NSCLC patients with wild-type EGFR.25 PFS was 1.6 months versus 4.8 months (HR 0.51, P<0.001), ORR was 14.7% versus 13.3% (P=0.814), and DCR was 32.0% versus 61.3% (P<0.001) for the gefitinib arm and pemetrexed arm, respectively. These results showed that patients with wild-type EGFR did not benefit from EGFR TKIs compared with chemotherapy in the second-line setting.

**First-line therapy for advanced NSCLC**

In preclinical models, the antitumor activity of erlotinib was enhanced in combination with chemotherapy. The efficacy of erlotinib in combination with chemotherapy as first-line treatment of advanced NSCLC was evaluated in two large, multicenter, randomized, placebo-controlled clinical trials: TRIBUTE (Tarceva responses in conjunction with paclitaxel and carboplatin)26 and the Tarceva Lung Cancer Investigation (TALENT; erlotinib plus cisplatin and gemcitabine) trails.27 However, neither study demonstrated that concurrent combination of erlotinib and chemotherapy improved efficacy, and thus this drug was not recommended as first-line treatment for advanced unselected NSCLC patients. Therefore, it is necessary to identify patients who may benefit from first-line EGFR TKI therapy.

The Iressa Pan-Asia Study (iPASS), a multicenter, Phase III, randomized study to compare gefitinib with carboplatin plus paclitaxel as first-line treatment in clinically selected patients in East Asia,28 highlights that EGFR-mutant lung cancer is a distinct subgroup for EGFR TKI treatment with superior clinical outcomes. Subsequently, two Japanese trials comparing first-line gefitinib versus chemotherapy for exclusive EGFR-mutant lung cancers confirmed the conclusion of iPASS.29,30 Therefore, the OPTIMAL (Erlotinib Versus Gemcitabine/Carboplatin in Chemo-naive Stage IIIIB/IV non-Small Cell Lung Cancer Patients with Epidermal Growth Factor Receptor [EGFR] Exon 19 or 21 Mutation [ML20981]; CTONG 0802) study was initiated to compare the efficacy and tolerability of first-line erlotinib versus gemcitabine plus carboplatin (GC) in advanced or metastatic NSCLC patients harboring activating EGFR mutations in the PRC28 (Table 2). The primary end point was PFS, and secondary end points included OS, quality of life, and RR. A total of 165 patients were randomized to treatment, and 154 patients received at least one dose of the study drug. In the OPTIMAL study, erlotinib was significantly superior to chemotherapy in terms of PFS, with median PFS of 13.1 months versus 4.6 months (HR 0.16, 95% confidence internal [CI] 0.10–0.26; P<0.0001). The subgroup analysis showed that almost all subgroups (sex, histology, and smoking status) obtained more clinical benefits from erlotinib than from chemotherapy. The ORR was 83% (68 of 82) for erlotinib and 36% (26 of 72) for chemotherapy (P<0.0001). As with PFS, response to erlotinib was similar across clinical subgroups. In terms of safety, erlotinib proved to be better tolerated than chemotherapy. Erlotinib was associated with less grade 3 or 4 toxic effects than chemotherapy (including neutropenia in 30 of 72 patients and thrombocytopenia in 29 patients on chemotherapy versus no patients with either event on erlotinib); the most common grade 3 or 4 toxic effects with erlotinib were increased alanine aminotransferase concentrations (4%, three of 83) and skin rash (2%, two of 83).

Another Phase III clinical trial, which was performed in Europe – EUROPean Tarceva vs Chemotherapy (EURTAC) – also showed that when compared with...
platinum-based chemotherapy as first-line treatment, erlotinib significantly extended PFS in the EGFR-mutant patients (9.7 versus 5.2 months, HR 0.37, 95% CI 0.25–0.54; \( P<0.0001 \)).\(^1\) RR was also higher in the erlotinib group (58% versus 15%). Main grade 3 or 4 toxicities were rash (13% given erlotinib versus none in the chemotherapy group), neutropenia (none versus 22%), anemia (1% versus 4%), and increased aminotransferase concentrations (2% versus 0). Five (6%) patients on erlotinib had treatment-related severe AEs compared with 16 patients (20%) on chemotherapy.

Based on the encouraging results of these randomized Phase III studies, which confirmed the role of first-line erlotinib in patients with activating EGFR mutations, erlotinib has been approved to be used as standard first-line treatment in EGFR mutation-positive NSCLC patients.

However, notably, OS benefit was not observed in these studies (median OS, OPTIMAL erlotinib versus GC, HR 1.065, \( P=0.6849 \); EUARTAC erlotinib versus platinum-based chemotherapy, HR 1.36, \( P=0.71 \)). This could be explained by the crossover of treatments after progression. The released survival analysis revealed that median OS of patients exposed to both chemotherapy and erlotinib (in any line of treatment) was 30.4 months compared with 20.7 months in patients exposed to erlotinib only, and 11.7 months in patients exposed to chemotherapy only. Thus, for patients with activating EGFR mutations, it may be an optimal strategy to receive both chemotherapy and erlotinib treatment, regardless of the order of use. However, to date, there has been no robust evidence to show significant differences in PFS and OS between patients receiving first-line erlotinib and those receiving second-line erlotinib. Therefore, should erlotinib be used in early treatment or later is still a problem to solve. For this reason, a Phase III clinical trial (ENSURE [A Study of Tarceva {Erlotinib} Versus Gemcitabine/Cisplatin as First-Line Treatment in Patients with Non-Small Cell Lung Cancer with EGFR Mutations]; NCT01342965)\(^1\) in the PRC is under way to compare the benefit of first-line versus second-line erlotinib treatment in patients with activating EGFR mutations. In this trial, patients were randomized to receive either erlotinib or 3-week cycles of a GC regimen until disease progression or unacceptable toxicity occurs (or up to four cycles of combined chemotherapy), and then two groups were crossed over to the opposite treatment. Further mature data is needed to evaluate this issue.

### Sequential intercalated combination regimens of chemotherapy and erlotinib

It is important to note that activating EGFR mutations were found in only 30%–40% of Chinese patients with adenocarcinoma, not to mention that the take-up rate of EGFR-mutation testing was only 10%, which means that EGFR-mutation status might still be unknown in most patients at the time when decisions are made regarding their first-line treatments.\(^2\) For these patients, a combination of chemotherapy and EGFR TKIs might be an optimal option. Even though previous Phase III studies in unselected populations showed that a combination of chemotherapy and erlotinib did not improve survival compared with chemotherapy alone,\(^26,27\) sequential intercalated combination regimens of chemotherapy and erlotinib (FASTACT [First-line Asian Sequential Tarceva And Chemotherapy Trial]) have been shown to induce significant improvement in responses and PFS, especially in patients with adenocarcinoma.\(^3\)

To confirm this finding, FASTACT-2 was launched by Wu et al in the PRC and other Asian countries.\(^4\) In this Phase III trial, patients with untreated stage IIIB/IV NSCLC were randomly assigned in a 1:1 ratio to receive six cycles of gemcitabine plus platinum with intercalated erlotinib (150 mg/ day on days 15–28, orally; chemotherapy plus erlotinib) or placebo orally (chemotherapy plus placebo) every 4 weeks. Patients continued to receive erlotinib or placebo until progression, unacceptable toxicity, or death, and all patients

**Abbreviations:** PFS, progression-free survival; ORR, objective response rate; OS, overall survival; Cis, cisplatin; Carbo, carboplatin; Pac, paclitaxel; Doc, docetaxel; Gem, gemcitabine; HR, hazard ratio; IPASS, Iressa Pan-Asia Study; EURTAC, EUROpean TARceva vs Chemotherapy.
in the placebo group were offered second-line erlotinib at the time of progression. A total of 451 patients were randomly assigned to chemotherapy plus erlotinib (n=226) or chemotherapy plus placebo (n=225). PFS was significantly prolonged with chemotherapy plus erlotinib versus chemotherapy plus placebo (median PFS 7.6 months versus 6.0 months, HR 0.57; \( P\lt 0.0001 \)). Median OS for patients in the chemotherapy-plus-erlotinib and chemotherapy-plus-placebo groups was 18.3 months and 15.2 months, respectively (HR 0.79, \( P = 0.0420 \)). A statistically significant treatment benefit was observed in patients with an activating EGFR gene mutation (median PFS 16.8 months versus 6.0 months, HR 0.25, \( P\lt 0.0001 \); median OS 31.4 months versus 20.6 months, HR 0.48, \( P = 0.0092 \)). Although no significant difference was observed in either median PFS or OS in patients with EGFR wild-type disease in the chemotherapy-plus-erlotinib group versus those in the chemotherapy-plus-placebo group, median PFS (7.1 months versus 6.0 months, HR 0.61; \( P = 0.0009 \)) significantly improved in patients with unknown EGFR-mutation status, revealing that the intercalated combination of chemotherapy and EGFR TKIs could be a reasonable treatment option for patients with an unknown mutation status in whom clinical parameters are suggestive of a high incidence of EGFR mutations.

**Maintenance therapy**

Maintenance therapy, which is defined as “any treatment that is given to keep cancer from progressing after it has been successfully controlled by the appropriate first-line therapy”, has become an established paradigm in advanced NSCLC treatment.\(^{35}\) The rationale for this strategy is that continuous treatment could effectively delay disease progression and improve survival. Nowadays, various agents have been applied in maintenance regimens, such as bevacizumab,\(^{36,37}\) cetuximab,\(^{38,39}\) docetaxel,\(^{40}\) gemcitabine,\(^{41}\) and pemetrexed,\(^ {42,45}\) for switching or continuous maintenance therapy. However, of interest, the most robust results were observed in clinical trials that evaluated EGFR TKIs (erlotinib or gefitinib) as switch maintenance agents (Table 3).

SATURN (2010, Sequential Tarceva in UnResectable NSCLC), a Phase III study of erlotinib as maintenance treatment in patients with nonprogressive disease after first-line chemotherapy, confirmed the efficacy and safety of erlotinib in this setting.\(^ {44}\) A total of 1,949 patients received at least one dose of standard doublet chemotherapy in the run-in phase prior to randomization, of whom 889 patients had complete/partial response or stable disease after four cycles of standard chemotherapy and were randomized to receive erlotinib or placebo. Median PFS and OS were significantly longer with erlotinib than with placebo (median PFS 12.3 weeks versus 11.1 weeks, HR 0.71, \( P\lt 0.0001 \); median OS 12.0 versus 11.0 months, HR 0.81, \( P = 0.0088 \)). Biomarker analysis showed that there was no significant interaction for EGFR protein expression or EGFR copy number, but patients with EGFR-activating mutations in exons 19 or 21 derived significantly greater PFS benefit from maintenance erlotinib (HR 0.10, \( P\lt 0.0001 \)) compared with those with wild-type tumors (HR 0.780, \( P = 0.018 \); treatment-by-mutation interaction, \( P\lt 0.001 \)). However, EGFR mutation status did not predict for an OS benefit. The later INFORM (Gefitinib as maintenance therapy in patients with locally advanced or metastatic non-small cell lung cancer) study (2011, CTONG 0804) in the PRC further supported the important role of EGFR TKIs (gefitinib) in maintenance therapy for NSCLC.\(^ {45}\)

Subsequently, a retrospective subanalysis of efficacy and safety in Asian patients enrolled in the SATURN study was performed, since Asian patients were reported to gain more benefit from EGFR TKIs compared with non-Asian patients.\(^ {15}\) In the initial phase, 241 patients were enrolled from the E/SE Asian region, including 46 from the PRC. Of these patients, 125 (including 28 from the PRC) were randomized to receive either erlotinib (n=60) or placebo (n=65). Erlotinib-maintenance therapy significantly prolonged PFS compared with placebo in the overall Asian subpopulation.

(HR 0.57, \(P=0.0067\)) and also in the subgroup of Asian patients with EGFR immunohistochemistry (IHC)-positive status (HR 0.50, \(P=0.0057\)). There was a nonsignificant trend towards increased OS in the erlotinib treatment arm in the Asian subpopulation (HR 0.67, \(P=0.0931\)), which reached statistical significance in Asian patients with EGFR IHC-positive status (HR 0.53, \(P=0.0233\)). TTP was also significantly prolonged in the erlotinib arm versus the placebo arm in the Asian subpopulation (HR 0.54, \(P=0.0038\)). Furthermore, erlotinib treatment produced a significantly higher ORR compared with placebo (23.7% versus 4.8%, \(P=0.0025\)). These data showed that the survival benefits of erlotinib-maintenance therapy in the Asian subpopulation were consistent with those in the global SATURN population, for both the intention-to-treat population and the EGFR IHC-positive Asian subgroup. Meanwhile, erlotinib was generally well tolerated in Asian patients and did not impair quality of life compared with placebo. Thus, erlotinib-maintenance treatment provides a treatment option in Asian patients with advanced NSCLC who have not progressed after first-line chemotherapy. Unfortunately, the data are inherently less robust than those of the SATURN intention-to-treat population, due to the retrospective nature of the analysis. Moreover, the researchers were unable to evaluate efficacy outcomes by EGFR-mutation status, because of a lack of sample material for gene analysis in the Asian population.

Adjuvant and neoadjuvant therapy for early stage and locally advanced NSCLC

So far, there has been no sufficient evidence for EGFR TKIs to be used either as adjuvant or as neoadjuvant treatment in patients with early and locally advanced NSCLC. Surgery and radiation (with or without chemotherapy) are still the standard treatments for these patients.

There is no obvious role for EGFR TKIs as postoperative treatment in patients with stage II and IIIA disease. The National Cancer Institute of Canada BR.19 trial, which was designed to investigate the efficacy and tolerability of gefitinib in patients with completely resected NSCLC, showed that gefitinib did not improve disease-free survival or OS, even in 15 patients with \(EGFR\)-mutation-positive tumors. Different from the BR.19 trial, in another ongoing study – RADIANT (Randomized Double-blind Trial in Adjuvant NSCLC with Tarceva) – a large randomized trial of postoperative adjuvant erlotinib versus placebo, \(EGFR\) and \(KRAS\) mutations, circulating deoxyribonucleic acid, EGFR ligands, and other potential markers will be studied to investigate further the predictive values of these biomarkers for adjuvant therapy of erlotinib.57

Since patients harboring \(EGFR\)-activating mutations showed excellent response to EGFR TKIs in advanced settings, several studies were initiated to explore the role of EGFR TKIs in the adjuvant setting in selected subgroup of patients in the PRC. A randomized Phase III trial (CTONG 1104, NCT01405079) was conducted to compare gefitinib with adjuvant vinorelbine plus cisplatin in patients with surgically resected \(EGFR\)-mutation-positive adenocarcinoma. Another Phase II clinical trial (ML28280, NCT01410214) is underway to assess the efficacy and safety of erlotinib versus adjuvant vinorelbine plus cisplatin as adjuvant treatment in patients with stage IIIA NSCLC after complete resection with \(EGFR\)-activating mutations.

In addition, for patients with stage IIIA NSCLC, although concurrent chemoradiation therapy remains a recommended treatment, the optimal treatment paradigm is still not clearly defined. The efficacy and safety of erlotinib as neoadjuvant treatment in patients with stage IIIA-N2 NSCLC with \(EGFR\)-activating mutations is also being investigated. A Phase II study (NCT00605870) which evaluated the value of induction-erlotinib therapy before thoracotomy or radiotherapy in IIIA-N2 (confirmed by mediastinoscopy or positron emission tomography) NSCLC selected by \(EGFR\) gene analysis, has just finished enrollment and the results are to be published. The ongoing Erlotinib Versus Gemcitabine/Cisplatin as (Neo)Adjuvant Treatment in non-Small Cell Lung Cancer (EMERGING; CTONG1103, NCT01407822) study and another Phase II study (ML25444, NCT011217619) are trying to evaluate the efficacy and safety of erlotinib as (neo)adjuvant treatment in patients with stage IIIA-N2 NSCLC with \(EGFR\) mutations. These studies may provide encouraging evidence in the application of EGFR TKIs in adjuvant and neoadjuvant treatment in patients with early and locally advanced NSCLC in the near future.

Acquired resistance

Even though the initial response to erlotinib was dramatic, the majority of patients with \(EGFR\)-sensitive mutations suffered disease progression after a median of 10–14 months due to acquired resistance. Different from the sometimes-indolent nature of EGFR TKI-resistant tumors and the disease flare after withdrawal of EGFR TKIs, several strategies have been developed to overcome acquired resistance, including switching to cytotoxic therapies or irreversible EGFR inhibitors in combination with other signal inhibitors.
local therapy, or cytotoxic therapies. But the best treatment mode remains unclear.

To date, clinically, the tumor burden and performance status of patients have been the basis for our therapeutic decisions. In a previous study, the progression pattern was divided into three clinical modes to describe the diversity of EGFR TKI resistance: dramatic progression, gradual progression, and local progression. The difference in PFS and OS among the three groups was significant (P=0.007). Further analysis showed that continuous EGFR TKI treatment was superior to switching to chemotherapy in the gradual-progression cohort (OS 39.4 months versus 17.8 months, P=0.02), while patients in the dramatic-progression group demonstrated better survival with switching to chemotherapeutic regimens. However, despite the clinical features, it is still unclear if there is a biomarker that could effectively guide the choice of subsequent treatment after acquired resistance to EGFR TKIs. A few clinical trials are ongoing to investigate treatment strategies after EGFR TKI failure, including ASPIRATION (Phase II Study of Continued Erlotinib Beyond RECIST Progression in Asian Patients (Pts) with Epidermal Growth Factor Receptor [EGFR] Mutation-Positive non-Small Cell Lung Cancer [NSCLC]) and IMPRESS (A Study of IRESSA Treatment Beyond Progression in Addition to Chemotherapy Versus Chemotherapy Alone; NCT01544179). More importantly, deeper molecular characterization of the primary tumor or metastases by rebiopsy should be recommended to further explore the optimal treatment strategy when patients obtain acquired resistance.

**Conclusion**

In the beginning, erlotinib was considered to be used in combination with chemotherapy as the first-line treatment of advanced NSCLC, but it was proved to be ineffective. This could be explained by the hypothesis that a negative interaction occurs between EGFR TKIs and cytotoxic agents when they are given concurrently, and that there are no molecular biomarkers to identify appropriate patients. Subsequently, several randomized studies have demonstrated the promising efficacy of erlotinib in second-line or third-line for patients with advanced NSCLC, including the BR.21 and TRUST studies. Interestingly, further subgroup analysis revealed that the efficacy and safety outcomes of erlotinib in the Asian population were better than those observed in the non-Asian population. Unsurprisingly, in Chinese patients, significant survival benefit from erlotinib was also observed. The benefit was likely to be driven by the presence of high rates of EGFR mutations. However, so far, there appears to be insufficient evidence to suggest that Chinese patients with EGFR mutations benefit any more or less from EGFR TKI therapy than patients from other ethnicities with the same EGFR mutation.

On the basis of results from the OPTIMAL and EURTAC studies, erlotinib has been approved as standard first-line treatment for patients with activating EGFR mutations. The FASTACT-2 study was the first to report significant prolongation of OS in patients with activating EGFR-mutation NSCLC, which provided a new treatment mode. Nevertheless, more evidence is needed to determine the timing of EGFR TKI administration for a better survival outcome.

Maintenance therapy with erlotinib was shown to improve PFS and OS in the SATURN study. As a result, erlotinib monotherapy has been approved for patients with advanced NSCLC with nonprogressive disease after first-line platinum-based initial chemotherapy. Still, it is not clear whether all patients with nonprogressive disease should receive maintenance therapy, especially those with activating EGFR mutations, for the effect of erlotinib on OS did not reach statistical significance in these patients compared to patients with wild-type EGFR.

At present, there is no precise role for erlotinib in early stage and locally advanced-stage NSCLC in patients with EGFR mutations or in those with EGFR wild-type tumors. Additional well-designed randomized controlled trials are needed to explore the efficacy and safety of erlotinib in adjuvant and neoadjuvant settings.

In conclusion, treatment with erlotinib as first-line, second-line, subsequent and maintenance therapy could significantly delay disease progression and be well tolerated in patients harboring activating EGFR mutations. EGFR-mutation status is the strongest predictive biomarker for the efficacy of erlotinib treatment, and is more common in the Asian (including Chinese) population. Acquired resistance remains the restriction of durable long-term outcomes of erlotinib. Further efforts are needed to explore new strategies to improve the efficacy of erlotinib treatment in all settings and overcome the drug resistance as well.

OncoTargets and Therapy is an international, peer-reviewed, open access journal focusing on the pathological basis of all cancers, potential targets for therapy and treatment protocols employed to improve the management of cancer patients. The journal also focuses on the impact of management programs and new therapeutic agents and protocols on patient perspectives such as quality of life, adherence and satisfaction. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
