Background: Hyperuricemia has been proposed to be a risk factor for cardiovascular disease and chronic kidney disease. Since diabetes is often complicated by hypertension and hyperuricemia, efficient therapeutic strategy against these two complications is very important in diabetic treatment. It has been reported that the antihypertensive drug, irbesartan, inhibits the renal uric acid reabsorptive transporters, URAT1 and GLUT9; this result suggests that irbesartan decreases serum uric acid level (SUA).

Subjects and methods: A retrospective study of 107 patients with hypertension and diabetes was performed to analyze the effects of irbesartan on blood pressure, estimated glomerular filtration rate (eGFR), and SUA. The follow-up period was 6–12 months. Seventy percent of the patients were diagnosed with diabetic nephropathy stage II–IV. We excluded patients treated with drugs that influenced SUA. The multiple logistic regression analysis was introduced to identify the relative factors for SUA decline. The time-dependent SUA changes were examined in a mixed-linear model.

Results: Irbesartan reduced blood pressure significantly after 1, 6, and 12 months’ treatment. No subject showed significant change in eGFR from baseline level throughout the period. The multiple logistic regression analysis revealed that SUA baseline significantly influenced SUA decline after 6–12 months. In patients whose SUA baseline was ≥5.9 mg/dL, the SUA was significantly decreased from 6.6±0.16 mg/dL to 6.2±0.16 mg/dL (P=0.010), after 12 months’ irbesartan treatment. In the SUA baseline group, the SUA did not show significant change over the monitoring period.

Conclusion: Our results demonstrate that irbesartan reduces the risk of hyperuricemia. No decline in renal function was observed after the initiation of irbesartan treatment. The present report determines the criteria of SUA baseline for introducing an antihyperuricemic effect using irbesartan. Its antihypertensive effect coupled with SUA decline would be effective for the treatment of hypertension complicated by hyperuricemia.

Keywords: angiotensin-receptor blocker, diabetes, hypertension, hyperuricemia, serum uric acid

Introduction

Hyperuricemia has been reported to be an independent risk factor for hypertension,1,2 cardiovascular diseases,3 and kidney diseases.4 Approximately 25% of patients with hypertension have hyperuricemia,1 while approximately 30% of patients with hyperuricemia or gout have hypertension.2 In diabetic patients, hypertension and decreased renal function with hyperuricemia are major problems.3 Therefore, the effects of antihypertensive drugs on serum uric acid level (SUA), especially angiotensin II receptor blockers (ARBs), have been closely scrutinized in recent years.
We have examined the influence on SUA by ARBs and shown that one of the ARBs, irbesartan, inhibits uric acid (UA) transport via the renal UA transporters, urate transporter 1 (URAT1) and glucose transporter 9 (GLUT9).\(^\text{6}\) URAT1 is involved in lumen-to-cytosol reabsorption of UA at the apical membrane of proximal tubules,\(^\text{7}\) whereas GLUT9 functions as a UA efflux transporter from tubular cells at the basolateral membrane.\(^\text{8}\) Mutations of URAT1 or GLUT9 are associated with renal hypouricemia,\(^\text{9–11}\) indicating that these two transporters play a dominant role in renal UA reabsorption and regulation of SUA. We previously reported that irbesartan (100–500 µM) inhibited the uptake of UA via both URAT1 and GLUT9 in vitro.\(^\text{6}\) Losartan has been shown to increase urinary UA excretion and to decrease SUA.\(^\text{12}\) Losartan is associated with a lower risk of incident gout among patients with hypertension.\(^\text{13}\) Since losartan is not effective for hypouricemic patients harboring URAT1 mutation, it has been demonstrated that the uricosuric action of losartan is via the inhibition of URAT1.\(^\text{14}\) The URAT1 inhibitory effects of irbesartan exceeded those of losartan in vitro, and the results suggest that irbesartan has the effect of decreasing SUA through increasing urinary UA excretion.\(^\text{6}\) Except for losartan and irbesartan, ARBs have been reported to increase the risk of gout\(^\text{15}\) and to increase the SUA.\(^\text{15}\) If irbesartan decreases SUA, its multiple effects would also make it useful for the treatment of hypertension combined with hyperuricemia.

A large study was performed in hypertensive patients with hyperuricemia to examine the effects of irbesartan on SUA for 2 months.\(^\text{16}\) Although the SUA decrease was observed in irbesartan-treated subjects (from 7.06 mg/dL baseline to 6.85 mg/dL), it was not significant and was less than in those treated with losartan (from 7.09 mg/dL to 6.03 mg/dL).\(^\text{16}\) In contrast, irbesartan was reported to decrease SUA significantly in hypertensive patients with advanced chronic renal disease.\(^\text{17}\) Since inconsistent results have been reported regarding its effects on SUA, it is necessary to determine whether irbesartan has an SUA decreasing effect. In the present study, we investigated the effects of irbesartan on SUA in hypertensive diabetic patients treated with 50–150 mg irbesartan.

**Subjects and methods**

**Subjects**

The study was approved by the Ethics Committee of Tokyo University of Pharmacy and Life Sciences and carried out in accordance with recommendations from the Declaration of Helsinki. This was a retrospective study performed at a diabetic clinic in Chigasaki (Japan). The subjects were 134 stable diabetic outpatients treated with irbesartan for 6–12 months in 2011–2012. We excluded 27 patients treated with drugs that influenced SUA such as allopurinol, diuretics, or fenofibrate. The remaining 107 patients were examined in this study. Out of these, 72 patients had been previously treated with other ARBs and the medicine was switched to irbesartan (designated the ARBs–IRB switch group). Other patients were started on irbesartan as the first ARB (designated the IRB group). Diabetic nephropathy was staged according to an analysis of the urinary albumin excretion (UAEx) and eGFR as defined by the Japanese Society of Nephrology from the Japanese historical cohort study;\(^\text{18}\) stage I, UAEx <30 mg/g creatinine; stage II, 30≤ UAEx <300 mg/g creatinine; stage III, UAEx ≥300 mg/g creatinine or continuous proteinuria (0.5 g/g creatinine ≤); stage IV, eGFR <30 mL/min/1.73 m\(^2\). Seven patients had the complication of myocardial disease and four of them were treated with a calcium channel blocker in combination with irbesartan. Three other patients had stopped treatment with anticoagulant, calcium channel blocker or nitrate before irbesartan was started. The dose of irbesartan was 50–150 mg. The follow-up period was 12 months for 101 patients and 6 months for the other six patients. Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were recorded before irbesartan treatment (pre), at the beginning of the study (0 month), and 1, 3, 6, and 12 months after irbesartan was started. Serum creatinine (SCr) and SUA were measured at the same time point as SBP and DBP. Estimated glomerular filtration rate (eGFR) was calculated from SCr, sex, and patients’ age. The calculation formula defined by the Japanese Society of Nephrology is:

\[
\text{Male eGFR (mL/min/1.73 m}^2) = 194 \times \text{SCr (mg/dL)}^{-1.094} \times \text{age (years)}^{-0.287}
\]

\[
\text{Female eGFR (mL/min/1.73 m}^2) = 194 \times \text{SCr (mg/dL)}^{-1.094} \times \text{age (years)}^{-0.287} \times 0.739
\]

Baseline values were calculated as the average of values between pre-treatment examinations and month zero.

**Statistical analysis**

The data are presented as means ± SD. Student’s \(t\)-test was adopted to compare continuous variables and a value of \(P<0.05\) was considered significant. Univariate logistic regression analysis was used to identify the factors associated with SUA changes. SUA decline after 6 or 12 months’ irbesartan
treatment was employed as the dependent variable. We introduced significant ($P<0.05$) independent variables from the univariate analysis into multiple logistic regression analysis. The sex, history of alcohol intake, and diabetic disease duration were included in the multiple logistic regression analysis as independent variables. The receiver operating characteristic (ROC) curves were used to estimate the SUA cut-off point and this was determined to be where the sum of sensitivity and specificity was maximized. The Bonferroni multi-comparison test method was used when correcting for redundancy as required and $P$-values $<0.05$ were again considered to be statistically significant. To compare the time-series data, we introduced a mixed-linear model adjusted for the cutoff of SUA baseline ($<5.9$ mg/dL or $\geq 5.9$ mg/dL) and the treatment before irbesartan (the IRB group or the ARBs–IRB switch group) as fixed effects. Analyses were performed with subjects as random effects. Data were analyzed using SPSS statistical software package for Windows (v21.0; SPSS Inc., Chicago, IL, USA).

Results and discussion

Here, the SUA-depressing effect of irbesartan was investigated retrospectively in 107 hypertensive outpatients with diabetes. The clinical characteristics of the patients are shown in Table 1. Patients in the ARBs–IRB switch group had significantly lower baselines of SBP and DBP than those of the IRB group because of their antihypertensive treatment. The ARB treatment is reported to decrease blood glucose level and total cholesterol. In agreement with those reports, the ARBs–IRB switch group showed significantly lower glucose baseline and low density lipoprotein-cholesterol baseline than the IRB group (Table 1). There were no significant differences between baseline values of SCr and eGFR in the IRB and ARBs–IRB switch groups. The ARBs–IRB switch group had statistically significantly higher SUA baseline than the IRB group. The possibility of SUA increase by the pre-treatment of ARBs was examined in 53 cases from 72 patients of the ARBs–IRB switch group. The SUA at 6–12 months did not change significantly from the ARB-naïve baseline values. The number of patients who had elevated SUA from the start of ARB use was almost the same as that of patients with decreased SUA (Table S1). From those results, the ARB pre-treatment was estimated not to be correlated with SUA increase. The baseline values of BP, SCr, eGFR, and SUA of the patients diagnosed with diabetic nephropathy are shown in Table S2. The stages of diabetic nephropathy did not significantly influence these baseline values. No patients developed gout or showed renal stone formation during the study period.

(Continued)
The SUA of the subjects at the end of the study period was compared with the baseline values and the number of the patients with SUA decline was more than half of the patients (Table S3). Thus, we performed univariate logistic regression analysis to identify the factors that influenced SUA changes after 6–12 months (Table S4). SUA decline after 6–12 months was introduced as the dependent variable and some clinical factors were examined with positive effects for SUA changes. The SUA baseline tended to be higher in men than women (Table 1); however, sex was not found to be a significant relative factor for SUA changes (Table S4).

The dose of irbesartan, the BP or SCr baseline values, and existence of diabetic nephropathy (stage II and III) were not found to be correlated to SUA. Cardiovascular diseases such as myocardial disease, cerebrovascular disease, and arteriosclerosis showed no significant effect on the SUA changes. The univariate logistic regression analysis revealed that ARBs–IRB switch, a history of alcohol intake, and higher SUA baseline were significant relative factors in the final model. However, the SUA baseline tended to be higher in men than women (Table 1); however, sex was not found to be a significant relative factor for SUA changes (Table S4).

The eGFR did not change significantly from the baseline since irbesartan treatment started (Figure 1B).

The SUA of the subjects at the end of the study period was compared with the baseline values and the number of the patients with SUA decline was more than half of the patients (Table S3). Thus, we performed univariate logistic regression analysis to identify the factors that influenced SUA changes after 6–12 months (Table S4). SUA decline after 6–12 months was introduced as the dependent variable and some clinical factors were examined with positive effects for SUA changes. The SUA baseline tended to be higher in men than women (Table 1); however, sex was not found to be a significant relative factor for SUA changes (Table S4).
analysis suggested that the higher SUA baseline led to SUA decline after irbesartan treatment.

We performed an ROC analysis to determine the cutoff SUA baseline for evaluating dependence of its effect on SUA decreases (Figure S1). The ROC analysis showed that patients with ≥5.9 mg/dL SUA at baseline had a positive benefit in terms of SUA decline.

Based on the results of the ROC analysis, the subjects were classified into those with an SUA baseline <5.9 mg/dL and those ≥5.9 mg/dL. There was no significant difference in the SUA between the ARBs–IRB and IRB groups except at baseline (data not shown). The irbesartan efficacy on SUA decrease was validated with a mixed-linear model using the 5.9 mg/dL cutoff. The results are shown in Figure 2. The group with an SUA baseline <5.9 mg/dL showed no significant SUA changes during the study period with the mixed-linear model. Subjects in the SUA baseline ≥5.9 mg/dL group had significantly higher SUA than the other group over the monitoring period (P<0.001) and their SUA decreased gradually in a time-dependent manner, with a significant decrease observed at 12 months (from the SUA baseline value 6.6±0.16 mg/dL to 6.2±0.16 mg/dL, P=0.010 by the Bonferroni method).

**Conclusion**

The present study revealed that irbesartan showed a significant effect on SUA decline on patients with higher SUA baseline and that the effect of irbesartan was seen markedly in patients with SUA ≥5.9 mg/dL. This result demonstrates that irbesartan treatment could achieve a decrease of SUA in hyperuricemic patients. This multiple effect of irbesartan enables efficient treatment for diabetic patients with hypertension and hyperuricemia.
