Follow-up care for breast cancer survivors: improving patient outcomes

1Department of Pharmacy Administration, Duquesne University, Pittsburgh, PA, USA; 2Department of Molecular and Cell Biology, University of Connecticut, Storrs, CT, USA

Background: Appropriate follow-up care is important for improving health outcomes in breast cancer survivors (BCSs) and requires determination of the optimum intensity of clinical examination and surveillance, assessment of models of follow-up care such as primary care-based follow-up, an understanding of the goals of follow-up care, and unique psychosocial aspects of care for these patients. The objective of this systematic review was to identify studies focusing on follow-up care in BCSs from the patient’s and physician’s perspective or from patterns of care and to integrate primary empirical evidence on the different aspects of follow-up care from these studies.

Methods: A comprehensive literature review and evaluation was conducted for all relevant publications in English from January 1, 1990 to December 31, 2013 using electronic databases. Studies were included in the final review if they focused on BCS’s preferences and perceptions, physician’s perceptions, patterns of care, and effectiveness of follow-up care.

Results: A total of 47 studies assessing the different aspects of follow-up care were included in the review, with a majority of studies (n=13) evaluating the pattern of follow-up care in BCSs, followed by studies focusing on BCS’s perceptions (n=9) and preferences (n=9). Most of the studies reported variations in recommended frequency, duration, and intensity of follow-up care as well as frequency of mammogram screening. In addition, variations were noted in patient preferences for type of health care provider (specialist versus non-specialist). Further, BCSs perceived a lack of psychosocial support and information for management of side effects.

Conclusion: The studies reviewed, conducted in a range of settings, reflect variations in different aspects of follow-up care. Further, this review also provides useful insight into the unique concerns and needs of BCSs for follow-up care. Thus, clinicians and decision-makers need to understand BCS’s preferences in providing appropriate follow-up care tailored specifically for each patient.

Keywords: breast cancer, breast cancer survivors, follow-up care, outcomes, survivorship care

Introduction
Breast cancer is the second most common cancer among women worldwide and its incidence has increased over the past 3 decades in many parts of the world, with approximately 1.7 million new cases diagnosed in 2012.1,2 This accounts for about 12% of all new cancer cases and 25% of all cancers that affect women.1 Furthermore, breast cancer survival has increased significantly due to improvement in diagnosis and treatment programs; women diagnosed with early, node-negative breast cancer now have a 5-year survival of 95%–98%, especially in developed countries.3,4 The significant progress made in prolonging survival after breast cancer treatment has presented new challenges to health care professionals (HCPs) and patients.5 Breast cancer is...
a long-lasting illness as it presents various post-treatment issues pertaining to cancer and its related treatments, including short- and long-term side effects, comorbidities, and emotional issues (fear of recurrence, late episodes of depression) as well as risk of cancer recurrence. Thus, appropriate follow-up care is an important aspect of comprehensive care for breast cancer survivors (BCSs) for improving patient outcomes, including reduced morbidity and mortality, improved psychosocial well-being, quality of life (QoL), and overall patient satisfaction.

The post-treatment follow-up care of BCSs requires determination of the optimum intensity of clinical examination and surveillance, assessment of models of follow-up care, such as primary care-based follow-up, an understanding of the goals of follow-up care, and unique psychosocial aspects of the care for these patients. Further, there are well-established guidelines by the American Society of Clinical Oncology (ASCO), the National Comprehensive Cancer Network (NCCN), the National Institute for Health and Care Excellence (NICE), and other national and international agencies that provide recommendations for key elements of follow-up care for BCSs. These guidelines aim to assist HCPs with decision-making for the effective management of BCSs, thereby improving patient outcomes.

Providing routine post-treatment follow-up services to BCSs is a standard practice in most countries. However, previous research indicates that there are variations in different aspects of follow-up care, such as the delivery of follow-up care, frequency of breast cancer surveillance, and extent of necessary psychological support and rehabilitation interventions required for reducing comorbidities. Further, there is no evidence on how these variations in follow-up care impact patient outcomes such as morbidity and mortality. In addition, it is also important to understand how patients perceive follow-up care and identify the unmet needs of these patients as well as physicians’ perceptions of follow-up care and their recommendations for improving patient outcomes.

Thus, the overall objective of this systematic review was to identify studies focusing on follow-up care in BCSs from the patient’s and physician’s perspective or from patterns of care and to integrate primary empirical evidence on the different aspects of follow-up care from these studies. The specific objectives were: 1) to identify studies focusing on aspects of follow-up care in BCSs including BCS’s preferences and perceptions, physicians’ perceptions, patterns of care, and effectiveness of follow-up care and 2) to identify components for optimal follow-up care that might be helpful in addressing unique needs and preferences of BCSs.

Methods
Search strategy
Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, a systematic literature search was conducted from January 1, 1990 to December 31, 2013. The literature search was conducted using electronic databases including PubMed, psychINFO, Embase, CINAHL, and the Cochrane Database of Systematic Reviews. The search strategy included combinations of keywords related to breast cancer and follow-up care such as breast cancer, breast neoplasm, breast carcinoma, BCS, post-treatment, follow-up, follow-up care, surveillance, survivorship care, screening, monitoring, pattern of care, and clinical care. Stage 1 screening identified titles or abstracts related to the main topic of interest. Furthermore, bibliographies of selected articles and published reviews were screened for additional studies of relevance. Titles and abstracts reviewed in Stage 1 were screened against the inclusion criteria, described below, in Stage 2. Articles that met the inclusion criteria were then subjected to final review. The literature search process is illustrated in Figure 1.

Inclusion and exclusion criteria
The search was limited to studies in English language. The inclusion of studies was limited to only breast cancer; studies on cancer in general were excluded. Randomized clinical trials, review studies, and intervention studies were excluded. In addition, conference abstracts, dissertations, summary reports, case studies, commentaries, and editorials were also excluded. Articles were included in the final review if they focused on BCS’s preferences and perceptions, physicians’ perceptions, patterns of care, and effectiveness of follow-up care. For the purpose of this review, breast cancer survivorship was defined as the period following first diagnosis and curative treatment and before recurrence of cancer or death; studies on patients undergoing treatment were excluded.

Data extraction
For the studies evaluating follow-up care in BCSs, the following information was extracted: study purpose, country where the study was conducted, population characteristics (sample size, patient’s age, time since diagnosis, type of primary breast cancer treatment), study design, and key findings.

Results
Based on the literature search methodology, 47 studies met the inclusion/exclusion criteria and were subjected to final review. The studies focusing on follow-up care in BCSs...
have been conducted in different populations worldwide, most of them in the US (n = 19),27,33–36,41–43,46,53–59,63–65 followed by the UK (n = 10),26,31,32,39,40,45,51,52,61,62 and the Netherlands (n = 7).23,24,38,44,48,49,60 Regarding study design, survey-based design including questionnaires, interview, or web-based surveys, was the most common study design used for evaluating follow-up care for assessing BCS’s preferences or perceptions as well as physicians’ perceptions regarding follow-up care. Secondary databases including Surveillance Epidemiology and End Results-Medicare claims data, patient chart reviews, and data from hospital documents were used for evaluating patterns and effectiveness of follow-up care.

For the purpose of this review, results from the studies have been categorized into six groups. These include studies evaluating aspects of follow-up care: i) BCS’s preferences, ii) BCS’s perceptions, iii) HCP’s perceptions, iv) common perceptions of both BCSs and HCPs, v) patterns, and vi) effectiveness.

**BCS’s preferences for follow-up care**

Table 1 provides a summary of nine studies that evaluated BCS’s preferences for follow-up care.19–27 Most of the studies had moderate-to-large sample sizes ranging 79–465 patients, except for one study22 in which focus group interviews were conducted with 26 patients. These studies were conducted in young, middle, or older-aged individuals, with age ranging from 33–90 years.

Two studies examined the BCS’s preferences for HCP, where medical specialists were favored over non-specialists (for example, oncologist over primary care physician [PCP]).24,27 Mayer et al reported that follow-up visits to medical oncologists were preferred over PCPs or nurse practitioners for domains including reduced worry about cancer (odds ratio [OR]: 2.21; P < 0.001), reduced stress around the visit (OR: 1.40; P < 0.002), and improved effect on cancer survival (OR: 2.38; P < 0.001).26 Further, Jiwa et al reported that older patients preferred a breast cancer nurse (BCN) for a mammography and a general practitioner for physical exam or emotional support.24

Besides preference for HCP, availability of information on concerns such as long-term effects of treatment, nutrition/exercise, recurrence, and recommended follow-up schedule, was also a key element in survivorship care.21,22,26 In addition, BCS’s preferences included in-person visits to

physicians versus virtual visits and individualized content-based follow-up on physical and psychosocial effects. Further, a need for more intensive therapy was reported by patients who received adjuvant hormonal therapy. BCS’s perceptions of follow-up care

Table 2 provides a summary of nine studies that assessed BCS’s perceptions of follow-up care. Most of the studies had small sample sizes, ranging from 10–41 patients, except for two studies that had large sample sizes, ranging from 182–300 patients. Most of the population comprised middle- or older-aged individuals, with age ranging 49–61 years.

Two studies evaluated perceptions of Australian BCSs, where considerable overlap in follow-up with a multidisciplinary team of health care providers was perceived as an ongoing problem. In addition, inadequate interdisciplinary communication perceived by BCSs was reported by Mao et al. Further, two studies focused on perceptions of African-American BCSs, in which lack of information about post-treatment care was one of the barriers to follow-up care. Other impediments to follow-up care included, but were not limited to, fear of recurrence, lack of social support, and medical care costs. In addition, the study by Pennery et al reported that most of the patients perceived a lack of continuity in follow-up care, felt uncomfortable expressing emotional concerns, and were not satisfied with physical examinations.

Further, examining patients’ perceptions of quality of care, a report from Mao et al analyzed BCS’s perceptions of PCP’s survivorship care; 50%, 59%, and 41% of patients perceived their physicians as knowledgeable about cancer follow-up, late effects of cancer therapies, and treating symptoms related to cancer or cancer treatments, respectively. Only 28% indicated that there was adequate communication between their PCP and their specialist.

Perception of HCPs regarding BCS’s follow-up care

Table 3 summarizes seven studies focusing on the perception of HCPs regarding follow-up care. In these studies, HCPs perceived follow-up care as important for the detection of treatment-related morbidity, need for greater care coordination across institutions, and need for sustainability of follow-up care in their practices. In addition, these studies also provide insight into the current practices as reported by HCPs. For example, a survey of ASCO members reported variations in intensity of post-treatment surveillance, such as overuse of surveillance testing (blood tests, liver function tests) not recommended by ASCO guidelines. A study on Australian HCPs noted that about one-third of the specialists reported that follow-up intervals and duration were in accordance with the national guidelines. Similar results were reported by studies evaluating perceptions of HCPs on follow-up care practices in the Netherlands and the UK.

Perceptions of both BCs and HCPs regarding follow-up care

Table 4 summarizes three studies focusing on both BCS’s and HCP’s opinion on follow-up care. These studies highlight components of follow-up care that are commonly perceived by BCs and HCPs. For instance, for both patients and HCPs, the detection of recurrence was the most important purpose of follow-up. Further, both HCPs and African-American BCs considered written survivorship care plans helpful for follow-up care.

Patterns of follow-up care in BCs

Table 5 summarizes 13 studies assessing the patterns of follow-up care in BCs. Five studies examined the pattern of mammography utilization or surveillance testing in the US population consisting of older BCs (≥65 years) during follow-up. Most of the patients (82%) had a mammography during the first year after treatment; the percentage declined to 68.5% by the fourth year of follow-up. Similarly, visits to a medical oncologist also declined after year 1; the percentage of patients seeing a medical oncologist decreased from 50% in year 1 to 27% by year 3. One of the studies noted that women visiting a medical oncologist (breast cancer surgeon: OR: 6.0; 95% CI: 4.9–7.4 and oncologist: OR: 7.4; 95% CI: 6.1–9.0) were more likely to receive a mammography compared to visits to PCPs. Further, Etim et al reported that women who had follow-up visits with both generalists and breast cancer specialists were more likely to receive a mammography versus those seeing only one HCP (OR: 2.13; 95% CI: 1.74–2.58).

Eight studies examined the pattern of surveillance in women aged ≥20 years. One study reported that the number of consultations among women who underwent radiotherapy were significantly higher (P<0.01) from second through to the fifth year compared to that in the first year and mammography was performed during 97% of consultations. However, another study reported a decrease in the number of follow-up visits and mammography, where at fifth year, follow-up visits declined to 16.1%, and 33.1% had fewer than the recommended number of mammogram screenings; decline in mammography was reported in older patients.

Effectiveness of follow-up care in BCSs

Table 6 summarizes six studies assessing the effectiveness of follow-up care in BCSs, where each study evaluated a different outcome including mortality, detection of recurrence, increase in surveillance testing, and reduction in anxiety. For example, the results of two studies showed that surveillance mammography was effective in reducing breast cancer mortality. However, one study noted that routine follow-up after curative treatment was inefficient in the detection of recurrence. These findings suggest that effectiveness of follow-up care components remains uncertain.

Discussion

Based on the 2012 World Health Organization report on breast cancer statistics, there were about 6.3 million women alive who had been diagnosed with breast cancer in the past 5 years. A steady increase in this number may place a significant burden on the medical community responsible for post-treatment follow-up care in providing optimal care and meeting BCS’s expectations to improve survivorship outcomes. In order to optimize post-treatment follow-up care, it is important to understand the goals of follow-up, including monitoring and managing short- and long-term cancer and its treatment-related side effects, detection of local, regional, and/or systemic recurrence, diagnosis of new primary breast cancers or other cancers, and psychosocial survivorship support. The challenge to the medical community is to objectively provide follow-up care to a diverse population with variable needs, ie, evidence-based follow-up that improves patient outcomes. There are practice guidelines for follow-up care that provide recommendations on follow-up care components including intensity, length, and frequency of follow-up care, surveillance testing for breast cancer, and coordination of care. However, these guidelines do not account for the individual variations among patients and cannot substitute for the independent professional judgment of a clinician. Thus, each of these components of follow-up care discussed below vary with individual needs and it is difficult to assess the importance of one component over another. This review summarizes evidence reported in the past 24 years that may help in understanding different components of follow-up care (Figure 2).

Intensive versus standard follow-up care

Intensive follow-up includes various tests, such as full blood count, biochemical assessment, tumor marker CA15-3, chest X-ray, and regular liver ultrasound and bone scan, whereas standard follow-up refers to clinical assessment and annual mammography. Generally, intensive follow-up is not recommended by the guidelines and there is no evidence demonstrating that it improves survival, QoL, or reduction in morbidity. Further, it has been suggested that QoL is negatively affected by invasive procedures used in intensive follow-up, possibly because of over-treatment and anxiety resulting from false-positive test results. However, studies included in this review suggest that intensive follow-up is frequently used. For instance, ASCO members reported that complete blood count and liver function test were most commonly recommended alongside routine clinical assessment.

Further, receipt of adjuvant hormonal therapy or radiotherapy was associated with a more intensive follow-up, as suggested by one of the studies. In addition, intensive follow-up was also reported to be influenced by factors such as patient preferences, treatment, or clinical factors. Further research is needed for understanding the factors that affect the decision of standard versus intensive care.

Frequency and duration of follow-up care

Both HCPs and BCSs view follow-up visits to be important for early detection of recurrence. In addition, BCSs also expect management of ongoing problems related to cancer or its treatments and availability of psychosocial support. Studies included in this review also suggest a variation from standard follow-up care recommended by guidelines and note various factors such as type of primary treatment, breast cancer stage, and patient’s age that influence the frequency of follow-up services. Based on the findings of this review, it appears that the periodicity of visits should be individually tailored to the observed timings of recurrence, with the goal of diagnosing local, regional, or systemic recurrence in combination with individual needs, including type of cancer, type of primary treatment received, the patient’s medical history, and overall health, including possible treatment-related problems. The Canadian Medical Association also recommends that the frequency and length of the follow-up service should be tailored to meet the needs of individual patients with at least one visit every 12 months. However, the data to address the optimal frequency of follow-up visits is limited. This necessitates further research to ascertain the optimal frequency and duration of follow-up visits and under what circumstances these components can vary.

Type of HCP for providing follow-up care

The evaluation and management of post-treatment follow-up of the patient with breast cancer generally involves HCPs of several disciplines including a PCP, BCN, and medical oncologist. Follow-up with multiple physicians is not only costly, but results in duplication of effort, and has not been shown to improve outcomes. Further, patients managed by a multidisciplinary team of HCPs perceived a significant overlap in follow-up care because of the lack of communication in the multidisciplinary care setting. Thus, for effective follow-up care and to improve patient outcomes, there should be coordination among HCPs of different disciplines.

Besides coordination of care, another important aspect is the specialist versus non-specialist model of follow-up care. Given the number of women treated for breast cancer, the frequency of recommended follow-up visits, and the limited availability of resources such as time and specialists, follow-up care after primary treatment of breast cancer is a major activity in departments such as medical oncology, and surgical or radiation oncology. Therefore, non-specialist-led follow-up care has been proposed as an alternative to specialist care for post-treatment management of cancer patients. However, there is little empirical evidence to address this controversy regarding specialist- versus non-specialist-led follow-up. Few studies included in this review have focused on this aspect, which suggests that specialist-led follow-up care was favored over non-specialist care and that fewer patients perceived their PCPs as having adequate knowledge of cancer follow-up and management of cancer-related side effects. Thus, the patient’s preference for a particular type of follow-up (ie, specialist versus non-specialist) should be taken into consideration in formulating a follow-up care plan. If a patient needs to be transferred from a specialist to a non-specialist, there should be clear recommendations for follow-up and in case of evidence of recurrent disease or specific concerns, there should be a way for referral back to the specialist.

Further studies should evaluate the factors underlying patient’s preferences for follow-up and compare the

effectiveness of care provided by different HCPs by assessing outcomes such as patient satisfaction, morbidity, and mortality. It is also important to identify the training needs of non-specialist HCPs to deliver quality follow-up care, thereby improving patient satisfaction with non-specialist-led follow-up care.

**Involvement of BCSs in follow-up care**

As discussed earlier, the purpose of follow-up care is not only the detection of recurrence, but also to meet patients’ expectations for follow-up. The long-term sequelae of breast cancer and its treatment necessitate the management of related side effects and complications. Our review findings suggest that patients have certain expectations regarding the availability of information on concerns such as short- and long-term physical effects of cancer and psychosocial support, which require the involvement of patients in decision-making. One study investigated the effect of patient-driven decision-making in follow-up care; patients with more involvement in decision-making reported better QoL. Thus, involvement of patients in decision-making can be useful in designing patient-centered care plans, thereby improving patient satisfaction and outcomes. Additionally, provision of necessary information can help patients make informed decisions as well as reduce post-treatment morbidity by involving themselves in self-care practices such as breast self-examinations. One of the studies examining preferences of African-American BCSs reported that the study subjects expected evidence-based information and guidelines from their HCP and expressed strong interest in self-care practices aimed at early detection of recurrence. However, there is a lack of published evidence focusing on the extent of patients’ involvement in decision-making. Further research focusing on the involvement of patients in decisions about their follow-up care and its impact on patient outcomes is needed.

**Surveillance testing for breast cancer follow-up care**

Women with a history of breast cancer are at an increased risk of development of contralateral breast cancer (CBC). Mammographic screening is the cornerstone of surveillance, especially for CBC and recommended by guidelines as an effective method for the detection of breast cancer at an early stage. The studies included in this review shed light on the variations in mammographic screening and suggest that there is underutilization of this screening in certain groups of patients. One of the studies reported that underutilization of mammography was more likely in women who are older, of black or Hispanic ethnicity, and in patients not seeing a medical oncologist. Certain barriers to follow-up care have been reported in African-American BCSs, which include fear of recurrence, lack of social support, and medical care costs. Additionally, findings from these studies suggest that the majority of patients had either fewer or greater than the recommended number of surveillance mammographies, indicating a variation from guidelines.

Detection of recurrence at a later stage could result in a higher rate of mortality. Thus, in order to improve patient outcomes, it is important to understand the underlying reasons for these variations to optimize the frequency of surveillance testing.

**Provision of psychosocial support in follow-up care**

Psychological support and reassurance for the patient by their HCP is one of the important primary goals of follow-up care. There are two important psychosocial issues that BCSs face; one is how cancer diagnosis and treatment affects their immediate family and their social relationships and second is how it affects the woman’s own identity (self-concept, body image, and sexuality), which results in problems such as anxiety, depression, and post-traumatic stress disorder. HCPs can provide emotional and social support by assessing their emotional status at each visit, addressing their fear and concerns, and providing information on patient counseling and arranging referrals. Additionally, BCSs can have social support from their family and friends, peer support programs, telephone support programs, and psycho-educational groups. However, there is a lack of evidence on the type of psychosocial support available to patients and the role of HCPs in providing psychosocial support during follow-up care and its effect on patient outcomes or QoL. A few studies have focused on patient perceptions of follow-up care, where most of the patients perceived a lack of continuity in follow-up care, lack of psychosocial support, and felt uncomfortable expressing emotional concerns. It is likely that provision of psychosocial support or lack thereof may, however, indirectly affect patient outcomes by influencing the patient’s choice of HCP, and the frequency and duration of follow-up care.

**Management of short- and long-term side effects**

Studies included in this review reported that BCSs preferred information on long-term effects of treatment. Findings from these studies also suggest that from a patient’s perspective, diagnosis of side effects was not the central aim of clinicians. Thus, in order to improve QoL, it is important for clinicians to provide adequate information on side effects...
and complications. Moreover, a patient-centered approach may be helpful in providing robust and uniform follow-up care for all patients as well as reducing cancer and treatment-related morbidity.

Conclusion

The studies reviewed, conducted in a range of settings, reflect variations in different aspects of follow-up care. Given such variations, future research is needed to better understand the complexity of different factors underlying these variations in order to optimize follow-up care. Further, this review also provides useful insight into the unique concerns and needs of BCSs for follow-up care. Thus, clinicians and decision-makers need to understand BCS’s preferences in providing appropriate follow-up care tailored specifically for each patient.
