Background: To date, the decision to treat multilevel cervical spondylotic myelopathy (CSM) with anterior cervical discectomy and fusion (ACDF) or anterior cervical corpectomy and fusion (ACCF) remains controversial. Therefore, we conducted a meta-analysis to quantitatively determine the efficacy of ACDF and ACCF in the treatment of multilevel CSM.

Methods: We searched several databases for related research articles published in English or Chinese. We extracted and assessed the data independently. We determined the pooled data, data heterogeneity, and overall effect, respectively.

Results: We identified 15 eligible studies with 1,368 patients. We found that blood loss and numbers of complications during surgery in ACDF were significantly less that in ACCF; however, other clinical outcomes, such as operation time, bone fusion failure, post Japanese Orthopedic Association scores, recovery rates, and visual analog scale scores between ACDF and ACCF with multilevel CSM were not significantly different.

Conclusion: Our results strongly suggest that surgical treatments of multilevel CSM are similar in terms of most clinical outcomes using ACDF or ACCF.

Keyword: meta-analysis, therapy, anterior cervical discectomy and fusion, anterior cervical corpectomy and fusion, cervical spondylotic myelopathy

Introduction
Cervical spondylotic myelopathy (CSM) is a common spinal disease caused by narrowing of the cervical spinal canal as a result of degenerative and congenital changes, and leads to significant neurological disability.¹⁻³ Except major cause of spinal degeneration, cervical congenital malformations that result in progressive scoliosis, such as developmental stenosis, may predispose to CSM. In addition to congenital cervical spinal stenosis, spontaneous fusion of the cervical vertebrae is a further type of congenital malformation that is also a known cause of CSM.⁴ Surgeries involving anterior and posterior approaches, including anterior cervical discectomy with fusion (ACDF),⁵⁻¹¹ anterior cervical corpectomy with fusion (ACCF),⁶⁻¹⁰,¹²⁻¹³ laminoplasty,¹⁴⁻²¹ laminectomy,¹⁹,²¹⁻²³ and laminectomy with fusion (class III),²⁶⁻³⁰ have been developed, and the functional outcome is improved after surgical treatment for CSM.³¹⁻³⁵ The surgical choice of an anterior, posterior, or combined approach for CSM should be based on the location and extent of compressive pathology, previous surgery, and the presence of preoperative neck pain, as well as the patient’s age and overall health conditions.³⁶⁻³⁸ Among the anterior approaches, ACCF has demonstrated relatively good fusion...
rates, but is associated with high morbidity of nonunion due to multiple graft-host interfaces, a higher incidence of complications including vertebral artery injury, dural tears, and cerebrospinal fluid leakage. ACDF is safe and effective for managing multilevel CSM, with a low prevalence of graft extrusion or migration; however, ACDF may have a high risk of incomplete decompression, limited visual exposure, and injury to the cord, as well as a high rate of pseudarthrosis secondary to an increase in the number of fusion surfaces. Therefore, to date, the decision to treat CSM, especially multilevel CSM, with ACDF or ACCF remains controversial. In the present study, we conducted a meta-analysis to quantitatively determine the efficacy of ACDF and ACCF in the treatment of multilevel CSM.

Materials and methods

We performed the meta-analysis according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses and the recommendations of the Cochrane Collaboration.

Data source and search

We searched and identified all published studies that compared the efficacy of ACDF and ACCF in the treatment of multilevel CSM. An extensive search of the literature was performed in Embase (1974 to July 2014), PubMed (1966 to July 2014) and the Cochrane Library, Biological Abstracts, Science Citation Index, Chinese BioMedical Literature Database, and China National Knowledge Infrastructure (1980 to July 2014). Medical Subject Headings were used to search in both the Chinese and English languages. We used the following keywords: cervical spondylotic myelopathy (CSM), anterior cervical discectomy and fusion (ACDF), anterior cervical corpectomy and fusion (ACCF). The full search strategy is available upon request from the corresponding authors. Relevant reviews and meta-analysis of surgeries in the treatment of CSM were also checked for the same reviewers. If additional data or clarification were necessary, we contacted the study authors. Any disagreements between initial reviewers were resolved by discussion with another reviewer until agreement was reached.

Data extraction

The data were extracted independently by two reviewers (ZL and HX). Data for publication information (name of first author, year of publication), study information (sample size and distributions of age and sex), and the effect of ACDF and ACCF in the treatment of multilevel CSM were collected using standard data extraction forms. The preoperative and postoperative Japanese Orthopedic Association (JOA) score, operation time, blood loss, surgical complications, neurological recovery rate, reoperation rate, as well as the recovery rates and the arm pain visual analog scale (VAS) scores were checked and extracted by the other two reviewers (GL and XL). The recovery rate was determined by the following equation:

\[
\text{Recovery rate} = \frac{\text{Preoperative JOA score} - \text{Postoperative JOA score}}{17 - \text{Preoperative JOA score}} \times 100\%
\]

Disagreement was checked again by a third reviewer (DL). Exclusion criteria were combined surgery, non-controlled studies, follow-up less than 1 year, and CSM caused by ossification of the posterior longitudinal ligament.

Statistical analysis

All statistical analyses were performed using RevMan version 5 from the Cochrane Collaboration. Odds ratios were calculated for binary outcomes and weighted mean differences for continuous outcomes, along with 95% confidence intervals. The pooled relative risks were combined by the Mantel–Haenszel method. The Peto method was used when there were trials with no events in one or both arms. Heterogeneity was evaluated using the \( \chi^2 \) test and \( F \) statistics (considered significant when the \( P \)-value for \( \chi^2 \) test was <0.10 or \( F \) was >50%). The level of significance was set at \( P<0.05 \). Fixed-effect models were applied unless statistical heterogeneity was significant, in which case random-effect models were used. We also assessed the probability of publication bias with funnel plots and the Egger’s test. We investigated the influence of study design (randomized controlled trial or quasi-randomized controlled trial) and fixed levels (short or long segment fixation) on pooled estimates using subgroup analysis.
Results

Study selection and characteristics

Five hundred and eleven relevant citations were selected for initial review according to the aforementioned search strategies and provided data regarding anterior cervical discectomy and corpectomy in patients with multilevel CSM. Of these, 496 were initially excluded after reading the abstracts and/or whole articles (Figure 1). Finally, the systematic literature search generated a total of 15 datasets and 1,368 patients for meta-analysis. The demographic data from studies included in the meta-analysis are shown in Table 1.

Methodological quality of the studies

Fifteen selected studies were evaluated to have high levels of methodological quality (more than six stars) according to the Newcastle–Ottawa quality assessment scale.56

Comparison of operation time between ACDF and ACCF for CSM

Seven studies with a total of 551 CSM patients who underwent either ACDF or ACCF surgery were meta-analyzed. Heterogeneity analysis shows that $I^2$ was 97%. The test for overall effect ($Z=0.78$, $P=0.43$) indicated that the operation time between ACDF and ACCF for CSM was not significantly different (Figure 2).

Comparison of blood loss between ACDF and ACCF for CSM

Seven studies reporting blood loss in a total of 551 CSM patients who underwent ACDF or ACCF surgery were also meta-analyzed. Heterogeneity analysis showed that $I^2$ was 98%. The test for overall effect ($Z=3.16$, $P=0.002$) indicated that blood loss between ACDF and ACCF for CSM was significantly different (Figure 3).

Comparison of bone fusion failure between ACDF and ACCF for CSM

Fourteen studies including bone fusion failure records in a total of 1,297 CSM patients with ACDF or ACCF surgery were meta-analyzed. Heterogeneity analysis shows that $I^2$ was 78%. The test for overall effect ($Z=0.8$, $P=0.42$) indicated that bone fusion failure between the two types of surgery was not significantly different (Figure 4).

Comparison of numbers of complications between ACDF and ACCF for CSM

Ten studies with a record of numbers of complications during or after ACDF or ACCF surgery in a total of 906 CSM patients were meta-analyzed. Heterogeneity analysis shows that $I^2$ was 46%. The test for overall effect ($Z=2.34$, $P=0.02$) indicated that numbers of complications between ACDF and ACCF for CSM was significantly different (Figure 5).

Comparison of post JOA scores between ACDF and ACCF for CSM

Nine studies with post JOA scores in a total of 674 CSM patients with ACDF or ACCF surgery were meta-analyzed. Heterogeneity analysis shows that $I^2$ was 88%. The test for overall effect ($Z=0.45$, $P=0.66$) indicated that post JOA scores between ACDF and ACCF for CSM were not significantly different (Figure 6).

Comparison of clinical outcomes between ACDF and ACCF for CSM

We determined the recovery rates for five studies in a total of 384 CSM patients with ACDF or ACCF surgery. Heterogeneity analysis shows that $I^2$ was 90%. The test for overall effect ($Z=0.71$, $P=0.48$) indicated that the recovery rates between ACDF and ACCF for CSM were not significantly different (Figure 7A). In addition, we also determined the

suggesting that there was no publication bias in the meta-
analysis of CSM patients with ACDF or ACCF surgery.

Discussion

Previous studies have shown that surgical treatments of
two-level CSM using ACDF or ACCF are similar in terms of clinical outcome. However, with regard to the amount of bleeding and radiological results, two-level ACDF was found to be superior to one-level ACCF in terms of operation times.49 Cunningham et al reviewed retrospective cohort stud-
ies comparing ACDF, corpectomy, laminoplasty, and

Figure 7 (A) Comparison of recovery rates between aCDF and aCCF for the treatment of CsM. (B) Comparison of visual analog scale scores between aCDF and aCCF for the treatment of CsM.

**Abbreviations:** aCDF, anterior cervical discectomy and fusion; aCCF, anterior cervical corpectomy and fusion; CsM, cervical spondylotic myelopathy; IV, independent variable; CI, confidence interval; SD, standard deviation.
laminectomy and fusion as surgical options for CSM from 1980 to January 2008, and concluded that all approaches yield similar neurorecovery rates.\textsuperscript{57} Recently, Shamji et al reviewed studies comparing multiple discectomies with single or multiple corpectomy, multiple discectomies with a hybrid discectomy–corpectomy procedure, and multiple corpectomies with a hybrid discectomy–corpectomy procedure, and concluded that all three operative approaches are effective strategies for the anterior surgical management of CSM.\textsuperscript{1} However, which surgery is a better option in the treatment of multilevel CSM remains unclear.

Based on 15 studies and a total of 1,368 cases of multilevel CSM using ACDF or ACCF, this pooled analysis comprehensively assessed the clinical outcomes after surgery. Using pooled analysis from the included studies, we found that although blood loss and numbers of complications in ACDF was significantly less than in ACCF, other clinical outcomes, such as operation time, bone fusion failure, and post JOA scores between ACDF and ACCF for multilevel CSM were not significantly different.

We did find evidence of publication bias, and consistent results are shown in sensitivity analyses. We should mention several potential limitations of this study. First, the searching strategy was restricted to articles published in the English or Chinese languages. Articles with potentially high-quality data that were published in other languages were not included because of anticipated difficulties in obtaining accurate medical translations. Second, the possibility of information and selection biases and unidentified confounders cannot be completely excluded because all of the included studies were observational. Hence, caution is advised when interpreting our findings and how they may relate to the general population.

Based on this meta-analysis of ACDF and ACCF for the treatment of CSM, we conclude that although blood loss and numbers of complications during surgery in ACDF were
significantly less that with ACCF, in terms of other clinical outcomes, such as operation time, bone fusion failure, post JOA scores, recovery rates, and VAS scores, there is no statistically significant difference between ACDF and ACCF for multilevel CSM were not significantly different.
