Background: We reported a 1-1-12 wash-in scheme for desflurane-nitrous oxide (N_2O) low flow anesthesia that is simple, rapid, and predictable. There remain some situations where N_2O should be avoided, which limits the generalizability of this wash-in scheme. The objective of our study was to determine the performance of this scheme in contexts where N_2O is not used.

Methods: We recruited 106 patients scheduled for elective surgery under general anesthesia. After induction and intubation, wash-in was started with a fresh gas flow of air: O_2 1:1 L/min and a vaporizer concentration of desflurane of 12%. Controlled ventilation was then adjusted to maintain $P_A CO_2$ at 30–35 mmHg.

Results: The alveolar concentration of desflurane ($F_A D$) rose rapidly from 0% to 6% in 4 minutes in the same pattern as observed in our previous study in which N_2O was used. An $F_A D$ of 7% was achieved in 6 minutes. An $F_A D$ of 1% to 7% occurred at 0.6, 1, 1.5, 2, 3, 4, and 6 minutes. The rise in heart rate during wash-in was statistically significant, although not clinically so. There was a slight but statistically significant decrease in blood pressure, but this had no clinical significance.

Conclusion: Performance of the 1-1-12 wash-in scheme is independent of the use of N_2O . Respective $F_A D$ s of 1%, 2%, 3%, 4%, 5%, 6%, and 7% can be expected at 0.6, 1, 1.5, 2, 3, 4, and 6 minutes.

Keywords: low flow anesthesia, wash-in, desflurane, air

Introduction

Low flow anesthesia (fresh gas flow [FGF] ≤ 1 L/min) is gaining in popularity because of its advantages (vis-à-vis economy, less pollution, and conservation of heat and humidity)¹ in addition to the availability of modern anesthetic machines and anesthetic gas monitors. Desflurane, with its properties of low blood and fat solubility and no limitation of FGF even with older CO_2 absorbers, is most suitable for low flow anesthesia.² Low flow anesthesia needs an initial wash-in phase to build up the required concentration of desflurane in the circle circuit ($F_I D$) and alveoli ($F_A D$).³ Most reported wash-in schemes need a very high FGF or vaporizer concentration of desflurane, yet achieve only some of the targeted $F_A D$.^{2,4,5} There is one scheme that can achieve every $F_A D$, but it is a complex logistic regression equation needing a computer to perform the calculation,⁶ so is inconvenient for everyday use. Recently, the authors reported a simple, single step 1-1-12 wash-in scheme using an FGF of $N_2O:O_2$ 1:1 L/min and desflurane 12%, that can rapidly yield every $F_A D$ from 1% to 6% within 4 minutes without tachycardia.⁷ Although N_2O is widely used because of its desirable effects (eg, analgesia and additive effect to the minimum alveolar concentration [MAC] of desflurane), there are still some situations where N_2O should not be used,^{8–11} which effectively

limits the generalizability of this scheme. The objective of the present study was to evaluate the 1-1-12 wash-in scheme in situations where N_2O is currently excluded.

Materials and methods

This study was approved by the institutional review board of Khon Kaen University (HE561247) and was registered at www.clinicaltrials.gov (NCT01348984). All patients gave their written informed consent before enrollment.

This was a descriptive trial. The sample size comprising 106 patients was determined in the same way as in our previous related study.⁷ We included patients with an American Society of Anesthesiologists physical status of I or II, aged 16–64 years, and scheduled for elective surgery under general anesthesia with endotracheal intubation and controlled ventilation. Patients with pulmonary or cardiac disease, a body mass index >30 kg/m², or a contraindication to use of succinylcholine were excluded.

All patients were managed by standard intraoperative monitoring and care in the same way as in our previous study.⁷ They were monitored with electrocardiography, pulse oximetry, noninvasive blood pressure measurement, capnography, and anesthetic gas analyzing equipment. The anesthetic machine, integrated with an anesthetic gas analyzer, used in this study was a Primus (Dräger AG, Lübeck, Germany). We used a standard circle circuit with a soda lime absorber. Each patient's heart rate and blood pressure were recorded before induction as a baseline measurement. The patients were then premedicated with intravenous fentanyl 1 µg/kg and induced with propofol 2 mg/kg. Intubation was facilitated with succinylcholine 1.5 mg/kg. Ventilation was controlled using an FGF of air: O_2 1:1 L/min and desflurane 12%. The initial ventilator setting was at a tidal volume 7 mL/kg and a respiratory rate of 12 per minute adjusted to keep the $P_A CO_2$ around 30–35 mmHg. The time to achieve an $F_A D$ at 1%, 2%, 3%, 4%, 5%, 6%, and 7% was recorded as the primary outcome. $F_i D$, heart rate, and blood pressure at each $F_A D$ were also recorded. After an $F_A D$ of 7% was achieved, FGF was reduced to 0.5–1 L/min and desflurane adjusted according to the judgment of the anesthesiologist.

Statistical analysis

The statistical analysis was performed using Statistical Package for the Social Sciences for Windows version 16.0 software (SPSS Inc, Chicago, IL, USA). Continuous demographic data are presented as the mean $\pm$ standard deviation and the categorical data as the number of patients (percentage). The primary outcome is presented as the mean $\pm$ standard

Table I Demographic data for the 106 patients

Parameter	Value
Age (years)	46.94 $\pm$ 15.19
Weight (kg)	58.56 $\pm$ 11.82
Height (cm)	159.18 $\pm$ 7.20
Sex	
Males	46 (43.4%)
Females	60 (56.6%)
ASA classification	
I	64 (60.4%)
II	42 (39.6%)

Notes: Data for age, weight, and height are presented as the mean $\pm$ standard deviation. Sex and ASA classification are presented as number of patients (%).

deviation and 95% confidence interval. The unpaired Student's *t*-test was used to compare the time and $F_i D$ to achieve each $F_A D$ in this study, consistent with our previous study.⁷ Heart rate and blood pressure values at different time points were compared using repeated measures analysis of variance. $P<0.05$ was considered to be statistically significant.

Results

In total, 106 patients participated in and completed the study. The demographic data for these patients are presented in Table 1.

The trajectories of time taken to reach each $F_A D$ by each patient during wash-in are presented in Figure 1. The times taken to achieve $F_A D$ from 1% to 7% and the 95% confidence intervals are presented in Table 2. Mean times in seconds were converted into approximate time in minutes for practical use. An $F_A D$ of 1%, 2%, 3%, 4%, 5%, 6%, and 7% can thus be expected at 0.6, 1, 1.5, 2, 3, 4, and 6 minutes, respectively.

Figure 1 Trajectories of time to achieve each $F_A D$ during wash-in.

Abbreviation: $F_A D$, alveolar concentration of desflurane.

Table 2 F_{AD} and time at different end points of F_{AD}

	F_{AD} (%)	Time (seconds)	95% CI (seconds)	Approximate mean time (minutes)
F_{AD} 1%	2.92±0.39	37.10±4.62	35.79–38.41	0.6
F_{AD} 2%	4.07±0.43	58.70±4.85	57.32–60.08	1.0
F_{AD} 3%	5.07±0.39	90.10±7.72	87.91–92.29	1.5
F_{AD} 4%	6.18±0.38	123.90±8.83	121.39–126.41	2.0
F_{AD} 5%	7.19±0.34	178.74±11.26	175.54–181.94	3.0
F_{AD} 6%	8.08±0.34	241.16±15.38	236.79–245.53	4.0
F_{AD} 7%	8.91±0.28	337.18±27.15	329.46–344.90	6.0

Note: Data are presented as the mean ± standard deviation.

Abbreviations: F_{ID} , inspired concentration of desflurane; CI, confidence interval; F_{AD} , alveolar concentration of desflurane.

The rising pattern of F_{AD} and F_{ID} is similar to that observed in our previous study,⁷ except for some statistically but not clinically significant differences at 5%, 6% and 4%, 5%, 6%, respectively (Figures 2 and 3).

The rise in heart rate during wash-in was statistically but not clinically significant (Figure 4). Blood pressure decreased slightly; this was statistically significant but not clinically so (Figure 5). These patterns are similar to those in our earlier study.⁷

Discussion

The pattern of the trajectories of time taken to achieve each F_{AD} in Figure 1 reveals that this scheme has acceptable intrasubject and intersubject variability. Although there are statistically significant differences in the increasing pattern of time and F_{ID} at some points of F_{AD} , these are in the order of a few seconds and not clinically significant. The times taken to achieve F_{AD} from 1% to 6% in this study (without N_2O as the carrying gas) is the

same as that reported in our previous study, which used N_2O as a part of FGF.⁷ The results of the present study show that the performance of the 1-1-12 wash-in scheme is not affected by the use of N_2O . The second gas effect of N_2O ¹² does not influence the uptake of desflurane because both N_2O and desflurane have nearly the same very low blood-gas solubility (0.47 versus 0.42). We extended the end point of F_{AD} in this study to 7%, which took 6 minutes to achieve, because without N_2O , which has an additive effect on the MAC of desflurane,¹³ a higher F_{AD} may be required to control the depth of anesthesia. The time required to increase F_{AD} from 6% to 7% was 2 minutes, which is double the time required to increase each 1% from 4% to 6%. This may be due to the narrower gradient between F_{ID} and F_{AD} at the high end of F_{AD} .

Our scheme requires less FGF, but can achieve each F_{AD} from 1% to 7% within 6 minutes, which is more rapid and simpler than most reported wash-in schemes. Baum et al used an FGF of 4.4 L/min and found that F_{AD} reached

Figure 2 Rising patterns of F_{AD} during wash-in when N_2O was included versus excluded.

90%–95% of the fresh gas concentration within 10–15 minutes.² Mapleson reported a spreadsheet model comprising two components: a circle circuit and a 70 kg anesthetized “standard man”, using an FGF equal to the total ventilation with 3 MAC of desflurane that could achieve an $F_{A}D$ of one MAC in 1 minute.⁴ Hendrickx et al used an FGF of $O_2:N_2O$ 2:4 L/min with desflurane 6.5% and found that an $F_{A}D$ of 4.5% could be achieved in 15 minutes.⁵

The aforementioned schemes used higher FGFs yet achieved only some specific $F_{A}D$ s. Hendrickx et al thus proposed an empirical model that could be used to predict FGF-desflurane combinations that achieved a target $F_{A}D$ within the first 5 minutes.⁶ Their model, however, is a complex logistic regression equation requiring a computer to calculate, mak-

ing it impractical for daily use. In comparison, our scheme is simpler and more practical, and yields a rapid wash-in with an expected $F_{A}D$ from 1% to 7% at 0.6, 1, 1.5, 2, 3, 4, and 6 minutes, respectively. This range of $F_{A}D$ covers the concentration for both balanced and pure inhalation anesthesia. This scheme can be applied with or without N_2O .

While Nyktari et al¹⁴ reported that a rapid increase in $F_{I}D$ to 1.5 MAC without the support of premedication caused a significant increase in airway resistance, we did not find such a problem. The explanation is that, with a lower FGF, an $F_{I}D$ of 1.5 MAC was gradually achieved in 7 minutes and fentanyl was used as a premedication.

In the current study, there was a statistically significant but not clinically increase in heart rate and decrease in blood pressure. This result is similar to our previous study using N_2O as a carrying gas⁷ and also consistent with the report by Warltier and Pagel,¹⁵ but different from the study by Ebert and Muzi,¹⁶ who reported hypertension and tachycardia in healthy volunteers receiving titration of desflurane from 1 to 1.5 MAC following thiopental induction. The explanation is that fentanyl, used as a premedication, attenuates sympathetic stimulation.¹⁷ Moreover, the rapid increase in $F_{I}D$ in our scheme (to the level exceeding the MAC of desflurane before the therapeutic level of the induction agent is on the wane) maintains the patient in the surgical stage throughout the study without sympathetic overactivity.

The 1-1-12 wash-in scheme has many advantages: simplicity (just one step for setting); coverage (every targeted $F_{A}D$ from 1% to 6% [7% where N_2O is omitted]); rapidity (achieving the targets within 0.6 to 4 minutes [6 minutes for 7%]); flexibility (applicable to situations both with or without N_2O); safety (wash-in without sympathetic overactivity); and economy (just 2 L/min of FGF and 12% desflurane). After achieving the required $F_{A}D$, the FGF can be reduced to a low flow anesthesia range of 0.5–1 L/min and the target $F_{A}D$ can be simply maintained by setting the desflurane above the $F_{A}D$ by 1%–2%.^{3,18}

Given that we excluded patients with a body mass index >30 kg/m², this scheme may not be generalized to such conditions, so further study is required.

Conclusion

The 1-1-12 wash-in scheme using a simple, single step FGF of N_2O or air: O_2 1:1 L/min and desflurane 12% for low flow anesthesia in patients requiring general anesthesia with endotracheal intubation and controlled ventilation has the same performance with or without N_2O . Each concentration of $F_{A}D$ from 1% to 7% can be expected at 0.6, 1, 1.5,

Figure 5 Blood pressure at different $F_{A}D$ during wash-in when N_2O was excluded.

Notes: Data are presented as the mean $\pm$ standard deviation. $P < 0.001$.

2, 3, 4, and 6 minutes, respectively. The 1-1-12 wash-in scheme covers the $F_A D$ required for both balanced and pure inhalation anesthesia. There were nonclinically significant increases in heart rate and decreases in blood pressure during this wash-in period.
