Abstract: Breast cancer is the most common cancer in the UK. Advances in the methods of early diagnosis as well as newer and more effective treatments have led to improvements of disease-free and overall survival over the last decade. Almost one-third of breast cancers present with an aggressive form characterized by increased expression of human epidermal growth receptor 2 (HER2) proteins. A targeted treatment using monoclonal antibodies against HER2 expression such as trastuzumab has been shown to improve survival. Unfortunately, there is a degree of cardiotoxicity associated with these agents, as inhibition of HER2 pathways can also impair cardioprotective pathways. In the present review, we discuss the mechanisms by which trastuzumab might affect vascular homeostasis leading to endothelial dysfunction. We also provide suggestions for future research examining the effects of trastuzumab on the vasculature in breast cancer.

Keywords: endothelial dysfunction, microvasculature, macrovasculature, congestive heart failure

Introduction

Breast cancer is the most common cancer in the UK and accounts for 30% of all new cancer cases in females with a greater incidence in women over the age of 60 years.¹ Fortunately, a variety of treatments including surgical resection, adjuvant chemotherapy, hormonal therapy, and radiation therapy have been shown to improve survival and reduce the risk of tumor recurrence. Approximately 15%–25% of patients present with aggressive breast cancer characterized by increased expression of human epidermal growth receptor 2 (HER2) proteins in the breast tissue.¹ It is postulated that HER2-positivity increases the likelihood of invasion and survival of tumor cells at the site of metastasis.² Therefore, patients with HER2-positive tumors may also have increased resistance to common anticancer treatments, such as chemotherapy and radiation therapy.²

In these patients, targeted treatment using monoclonal antibodies such as trastuzumab (Herceptin) can be used to reduce tumor recurrence and improve survival.^{3,4} Trastuzumab selectively binds to the extracellular domain of HER2 receptors, where it inhibits downstream signaling pathways, resulting in a reduced proliferation of tumor cells. This is achieved by identifying tumor cells for immune destruction, and then, by initiation of antibody-dependent cellular cytotoxicity, causing apoptosis of tumor cells.⁵ In addition, trastuzumab undergoes internalization (endocytosis) into the tumor cells and subsequently increases the expression of HER2 on the cellular surface. This enhances the immune effects of trastuzumab and reduces tumor expression.⁵ However, trastuzumab is also associated with an increased risk of cardiotoxicity

which manifests clinically as congestive heart failure (CHF).⁶ Trastuzumab-mediated cardiotoxicity appears to be independent of drug dose, has not been shown to be associated with structural changes in cardiomyocytes, and is fully reversible following cessation of treatment.⁷ Cardiotoxicity is more likely to occur in patients who have preexisting hypertension, a history of smoking, obesity, family history of cardiovascular disease (CVD), and previous coronary artery disease – all of which are well-established risk factors for cardiac events.^{8,9} CVD and its sequelae are strong predictors of mortality in patients with breast cancer, this association being independent of breast cancer stage.¹⁰ It is therefore possible that trastuzumab-related cardiotoxicity might be mediated by adverse drug effects on the coronary vasculature. In this review, we summarize the biological mechanisms by which trastuzumab may affect the vasculature and contribute to CVD risk. We also provide suggestions about the investigation of trastuzumab-mediated cardiotoxicity in future research studies.

The importance of HER2 and neuregulin

The human epidermal growth receptors are tyrosine-kinase receptors and are expressed as four isoforms: HER1, HER2, HER3, and HER4. The second isoform (HER2) regulates the growth, repair, and regeneration of breast tissue,¹¹ but overexpression of HER2 receptors via polymorphisms in the *erb-b2* receptor tyrosine kinase 2 oncogene can lead to uncontrolled cell growth.¹² This state is known as HER2-positivity and is linked with increased mortality.^{13,14} Under normal conditions, a protein called neuregulin is released by coronary microvascular endothelial cells and the endocardium.¹⁵ Neuregulin binds to HER4 receptors which dimerize with HER2 receptors and increase several survival pathways in the myocardium.¹⁵ The primary role of the survival pathways is to inhibit the production of reactive oxygen species (ROS) and maintain cellular integrity by reducing cell apoptosis. In an animal model of adult rat ventricular myocytes, treatment with either paclitaxel or trastuzumab resulted in damage to cardiac myofilaments which corresponded with increased intracellular calcium, reduced diastolic relaxation time, and increased oxidative stress.¹⁶ These adverse changes following trastuzumab increase the risk of developing CHF (for review, see Sandoo et al¹⁷). Indeed, the HER2/neuregulin pathway is integral to the preservation of sarcomeres in the cardiomyocytes.¹⁸ However, neuregulin can also increase the expression of endothelial nitric oxide synthase (eNOS).¹⁵ The eNOS gene is constitutively expressed in vascular endothelial cells and releases nitric oxide (NO) – a vasoactive

molecule that reduces oxidative stress and prevents atherosclerosis.¹⁹ NO bioavailability is increased via activation from protein kinase B as a result of the dimerization of HER2 and HER4 receptors.¹⁵ Trastuzumab blocks this dimerization and therefore inhibits the cardioprotective actions of neuregulin.²⁰ Given that the myocardium is a highly vascularized territory, it is possible that abnormalities in the vasculature following trastuzumab could also contribute to CHF. In the following section, we discuss the implications of blocking HER2 using trastuzumab on vascular endothelial cells, and highlight how this may contribute to cardiovascular complications in breast cancer.

Mechanisms for trastuzumab-mediated endothelial dysfunction eNOS

The endothelium is the delicate and permeable lining of the vasculature which allows specific vasoactive factors to regulate homeostatic processes and prevent atherosclerosis.¹⁹ In a healthy vessel, eNOS continuously synthesizes NO, helping to maintain basal vasodilator tone and preventing platelet aggregation and formation of ROS.¹⁹ In chronic disease states characterized by increased oxidative stress and low-grade chronic inflammation (such as breast cancer), endothelial cells can be damaged, leading to a reduction in eNOS expression and endothelial dysfunction.^{21,22}

The expression of eNOS has been postulated to play an important role in regulating cardiovascular function and overall survival in breast cancer. In a recent study, Zeglinski et al²³ compared 60 wild-type mice with 60 mice having a congenital absence of the eNOS gene treated with either saline, doxorubicin, or trastuzumab, or both drugs simultaneously. Following simultaneous treatment with both agents, the mice with absence of the eNOS gene presented with adverse modeling of the left ventricle, reduced left ventricular systolic function, increased oxidative stress, and reduced survival when compared with the wild-type mice. These findings suggest that adequate expression of the eNOS gene is important in suppressing the generation of ROS which may in turn improve cardiac function and survival following trastuzumab treatment. Indeed, in human breast cancer patients receiving chemotherapy, polymorphisms in the eNOS gene result in poorer survival,²⁴ and expression of eNOS in the microvessels surrounding breast tumors associates with better prognosis, possibly due to a reduction in tumor progression.²⁵ In addition, polymorphisms in the Asp298 allele of the eNOS gene result in impaired NO synthesis which reduces event-free survival in patients with systolic heart failure.²⁶

Generation of ROS

Inhibition of the neuregulin/HER2 pathway by trastuzumab allows increased production of ROS,¹⁵ due to abnormalities in mitochondrial respiration in cardiomyocytes, which increases myocardial stress.²⁷ When the myocardium is increasingly stressed, angiotensin II (ANG II), thrombin, platelet-derived growth factor, and tumor growth factor- α are upregulated and stimulate vascular smooth muscle cells to increase formation of further ROS.²² ANG II, which is a potent vasoconstrictor, also inhibits neuregulin activity in the coronary microvasculature and increases levels of nicotinamide adenine dinucleotide phosphate-oxidase (NADPH).^{28,29} NADPH has been implicated as a causal factor of endothelial dysfunction due to its ability to generate large amounts of ROS in the endothelium.²² The mechanisms highlighted above represent a vicious cycle of free radical formation which will injure the endothelium causing endothelial dysfunction (Figure 1).

Endothelial dysfunction and CHF

Treatment with trastuzumab does not cause morphological alterations to cardiomyocytes, and myocardial function can improve following cessation of treatment.³⁰ Although apoptosis of cardiomyocytes following trastuzumab treatment can result in CHF,³¹ in the general population, endothelial dysfunction is one of the primary causal factors for CHF.^{32–35} On this basis, it has been hypothesized that endothelial dysfunction

might be the principal mechanism for trastuzumab-mediated CHF (see Figure 2).¹⁷

The myocardial microvasculature receives less than 5% of cardiac output yet regulates the majority of blood flow to the myocardium.³⁶ Unsurprisingly, in a 5-year prospective study of 242 CHF patients, microvascular endothelial dysfunction was independently associated with cardiac events.³³ Similarly, Fischer et al³² revealed that large-vessel endothelial dysfunction was independently associated with higher incidence of hospitalization from CHF, cardiac transplantation, and cardiac death. These findings suggest that global alterations in the vasculature are important determinants for the development of CHF and associated comorbidities.

The central mechanisms in the development of CHF involve the reduction in L-arginine and tetrahydrobiopterin (BH₄) concentrations – both essential substrates for the synthesis of NO.³⁷ In particular, absence of the NO cofactor BH₄ can increase the production of ROS, perpetuating myocardial damage. The conversion of L-arginine to NO by eNOS requires the presence of BH₄ which helps the transfer of electrons produced at the eNOS site to an oxidase domain, resulting in activation of oxygen. The activated oxygen is then “coupled” with L-arginine oxidation to produce NO.³⁸ However, in the absence of BH₄ or L-arginine, eNOS produces superoxide molecules instead of NO.³⁸ Levels of BH₄ are reduced in CHF,³⁹ and the consequent reduction in NO will impact on coronary vasorelaxation and basal blood flow, both of which are important physiological factors for the development of CHF.⁴⁰

The renin–angiotensin system also plays an important role in regulating the release of NO from vascular endothelial cells. In CHF patients presenting with decreased vasodilatory function of the large arteries, angiotensin-converting enzyme (ACE) inhibitors improve vasodilatation as a result of increased NO bioavailability.⁴¹ Similarly, endothelial function improves following administration of ANG II receptor antagonists concomitantly with ACE inhibitors.⁴² In breast cancer patients treated with trastuzumab, concomitant administration of ACE inhibitors, ANG II receptor antagonists, and beta-blockers improves left ventricular ejection fraction over the course of treatment.⁴³ Given that trastuzumab can reduce NO production and increase production of ANG II via inhibition of neuregulin, it is plausible that CHF resulting from trastuzumab treatment is likely to be mediated, in part, by endothelial dysfunction of the coronary vasculature.

Role of classical CVD risk in potentiating trastuzumab-mediated cardiotoxicity

The link between endothelial dysfunction and development of CHF in trastuzumab-treated patients could be mediated

Figure 2 The effects of trastuzumab on the vasculature and its subsequent contribution to congestive heart failure.

Notes: Administration of trastuzumab inhibits HER2 receptors, which prevents dimerization with the neuregulin–HER4 complex. This subsequently causes a reduction in eNOS expression and NO bioavailability, along with a concomitant increase in ANG II and ROS. These processes culminate in endothelial dysfunction which is characterized by reduced vasodilatory capacity, enhanced vasoconstrictor tone, and endothelial injury. Endothelial dysfunction is a well-established causal factor for congestive heart failure because it increases systemic vascular resistance, afterload, and myocardial workload, but reduces coronary microvascular blood flow.

Abbreviations: ANG II, angiotensin II; eNOS, endothelial nitric oxide synthase; HER, human epidermal growth receptor; NO, nitric oxide; ROS, reactive oxygen species.

by several classical CVD risk factors. Associations between CVD risk factors implicated in endothelial dysfunction and trastuzumab-mediated cardiotoxicity have been reported.^{8,9} The presence of severe hypertension in particular appears to be an important factor in the development of heart failure following trastuzumab treatment.^{8,44} Hypertension usually occurs when NO bioavailability is reduced, allowing vasoconstrictors such as endothelin-1 and ANG II to increase systemic vascular resistance.⁴⁵ The direct consequence is an augmentation in afterload and intracavitary pressures of the left ventricle. If the increased myocardial stress is coupled with poor myocardial blood flow, cardiac workload will be increased, leading to profound damage of the myocardium and CHF.⁴⁶ Thus, the impact of CVD risk status is important in understanding the impact of trastuzumab treatment on the vasculature.

Proposals for future research studies

The investigation of endothelial dysfunction following trastuzumab treatment has received little attention in the literature to date, yet it is clear that abnormalities in the vasculature following inhibition of HER2 could be

implicated in the development of trastuzumab-mediated cardiotoxicity. At present, several noninvasive assessments which examine vasodilatory function and arterial structure can be utilized in patients with breast cancer.¹⁹ These peripheral vascular assessments correlate well with assessments in the coronary circulation^{47,48} and are strong predictors of cardiac events in a variety of clinical populations at risk of CVD,^{49,50} including postmenopausal women.⁵¹ Thus, we suggest that, in addition to further in vitro and animal model work, studies should also be conducted to 1) identify whether there is evidence of endothelial dysfunction in trastuzumab-treated patients when compared to non-trastuzumab-treated patients and healthy controls; 2) establish the time course of endothelial dysfunction by conducting long-term prospective studies examining endothelial function at pretreatment baseline and at multiple follow-up points; and 3) assess the impact of classical CVD risk factors and their control on the above. Such studies will enable better understanding of the processes that cause CHF following trastuzumab treatment, inform possible pharmacological and nonpharmacological interventions, and eventually improve cardiovascular outcomes in this patient population.

Vascular Health and Risk Management

Publish your work in this journal

Vascular Health and Risk Management is an international, peer-reviewed journal of therapeutics and risk management, focusing on concise rapid reporting of clinical studies on the processes involved in the maintenance of vascular health; the monitoring, prevention and treatment of vascular disease and its sequelae; and the involvement of

metabolic disorders, particularly diabetes. This journal is indexed on PubMed Central and MedLine. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <http://www.dovepress.com/vascular-health-and-risk-management-journal>
