Abstract: Hypertension and diabetes are clinical conditions which contribute to the development of chronic kidney disease as well as risk factors for cardiovascular events. In recent years, lipocalin-type-prostaglandin-D-synthase (beta trace protein; BTP) has increasingly been studied as an alternative to creatinine for the evaluation of renal function as well as for being a possible biomarker for cardiovascular disease. It is expected that the levels of BTP in patients with cardiovascular disease are elevated, as is the case with patients with renal dysfunction. The objective of this study is to realize a systematic review of the pertinent literature in respect to BTP as a biomarker of renal dysfunction in diabetic patients. Using the database MEDLINE, a search up to year 2014 was conducted using the follow descriptors: “lipocalin type prostaglandin d synthase” AND “diabetes”; “lipocalin type prostaglandin d synthase” and “diabetic nephropathy”; “beta trace protein” AND “diabetes”; “beta trace protein” AND “diabetic nephropathy”. The criteria used for inclusion were the presence of the referring to terms in title or abstract and study conducted in humans. About 17 articles were selected, of which six articles were duplicates, and of which six articles did not investigate any possible relationship between the protein (BTP) and either diabetes or nephropathy. The final result yielded five articles to be analyzed. This review found BTP is not influenced by race, by body mass index nor by patient’s sex. BTP can be considered as a reliable early biomarker of renal dysfunction in diabetics. BTP is associated with metabolic syndrome and is also associated with greater cardiovascular risk. Prospective data establishing a correlation between BTP and mortality would have been of great interest, but such articles were not found in this review.

Keywords: renal lesions, type 2 diabetes, lipocalin-type-prostaglandin-D-synthase, diabetes predictor

Introduction

Research has shown that both systemic hypertension and type 2 diabetes are multi-factorial clinical conditions which present metabolic alterations as well as alterations to the target organ. These alterations in turn result in an increased risk of cardiovascular events as well as renal insufficiency.1,2

Currently, the glomerular filtration rate (GFR) is considered to be the gold standard to measure renal function. However, given the limitations of creatinine as a biomarker of this GFR, and therefore of renal function, new alternative biomarkers are being investigated, such as low molecular weight proteins.3

Lipocalin-type-prostaglandin-D-synthase (or, beta trace protein, BTP) can be considered a protein with a double function: first, BTP acts as an enzyme in the production of PGD2; and second, after being secreted, BTP acts as an extracellular...
BTP, beta trace protein. GFR, glomerular filtration rate.

Recently interest has grown in the study of BTP as an alternative to serum creatinine for the evaluation of renal function as well as being a biomarker for cardiovascular diseases. The expression of BTP is not influenced by race, by body mass index, nor by the sex of the patient, when standardized to creatinine, to beta-2-microglobulin and to cystatin C.

In the last 10 years, only two articles have shown a direct relationship between alterations in BTP and either diabetes or kidney disease. Kobata et al showed the relationship between stages of diabetic nephropathy and BTP serum levels. There was a close relationship between higher levels of BTP in type 2 diabetic patients with macroalbuminuria but no renal dysfunction.

As a predictor of early renal dysfunction, urinary BTP levels better predicted kidney disease than other traditional biomarkers when albuminuria was present in levels higher than 30 mg/g creatinine. Also, in the prospective arm of the study, those without albuminuria but higher excretion of BTP had evolved with worse kidney function.

In newborns, BTP is promising as a marker of GFR because its level rises as the gestational period advances. Creatinine should increase because of the gain in muscle mass of the baby. Cystatin C is a protein that crosses the maternal placenta and a rise in its level might be due to the influence of maternal cystatin. Only BTP remains constant suggesting its performance as a better GFR marker in newborns than creatinine and cystatin.

Cheung et al and Yoshikawa et al found a positive association with BTP in patients with metabolic syndrome (MetS) and kidney damage. Their results showed a different interpretation according to where BTP was measured. Cheung et al gathered 3,136 participants aged ≥20 years from the National Health and Nutrition Examination Survey III. Patients with reduced serum levels of BTP were associated positively with MetS and worse GFR even after adjusted models by ethnicity, age, and sex.

Yoshikawa et al measured urinary levels of BTP in a cross-sectional study with type 2 diabetic Japanese patients. There was a direct association between the rise of urinary concentration of BTP and worse GFR and also MetS in this population. Though, the rate of cardiovascular events in the follow-up period was higher in those with higher urinary levels of BTP.

Articles containing prospective data establishing a correlation between BTP and either morbidity or mortality in the spectrum of kidney disease would have been of great interest however there were no such articles in the period studied.

In summary, BTP can be considered as a promising biomarker of kidney dysfunction in diabetes and is associated with the presence of MetS and greater cardiovascular risk.
