Objective: Our objective was to compare the clinical effectiveness of home blood pressure monitoring (HBPM) and 24-hour ambulatory blood pressure monitoring (ABPM) on blood pressure (BP) control and patient outcomes.

Design: A systematic review was conducted. We also appraised the methodological quality of studies.

Data sources: PubMed, Scopus, CINAHL, and the Cochrane Central Register of Control Trials (CENTRAL).

Inclusion criteria: Randomized control trials, prospective and retrospective cohort studies, observational studies, and case-control studies published in English from any year to present that describe HBPM and 24-hour ABPM and report on systolic and/or diastolic BP and/or heart attack, stroke, kidney failure and/or all-cause mortality for adult patients. Due to the nature of the question, studies with only untreated patients were not considered.

Results: Of 1,742 titles and abstractions independently reviewed by two reviewers, 137 studies met predetermined criteria for evaluation. Nineteen studies were identified as relevant and included in the paper. The common themes were that HBPM and ABPM correlated with cardiovascular events and mortality, and targeting HBPM or ABPM resulted in similar outcomes. Associations between BP measurement type and mortality differed by study population. Both the low sensitivity of office blood pressure monitoring (OBPM) to detect optimal BP control by ABPM and the added association of HBPM with cardiovascular mortality supported the routine use of HBPM in clinical practice. There was insufficient data to determine the benefit of using HBPM as a measurement standard for BP control.

Conclusion: HBPM encourages patient-centered care and improves BP control and patient outcomes. Given the limited number of studies with both HBPM and ABPM, these measurement types should be incorporated into the design of randomized clinical trials within hypertensive populations.

Keywords: ABPM, HBPM, OBPM, randomized control trials

Introduction

Based on scientific evidence, national and international guidelines recommend optimizing medication dosages or adding additional antihypertensive medication until target goal blood pressure (BP) is obtained.1,2 Obtaining a target goal BP is crucial to prevent poor outcomes such as cardiovascular disease, kidney failure, and stroke. However, approximately 53.5% of Americans are not at their target goal BP.3 While office blood pressure monitoring (OBPM) is the usual care or gold standard for hypertension control...
diagnosis and treatment, home blood pressure monitoring (HBPM) improves BP control and medication adherence. A 24-hour ambulatory blood pressure monitoring (ABPM) is useful where there is uncertainty in diagnosis, resistant treatment, irregular variation or concerns about variability, and white coat or masked hypertension. It has been shown that HBPM correlates with ABPM, and cost and inconvenience are reasons why ABPM is not routinely recommended for the evaluation of patients with essential hypertension. HBPM is “easy to perform, reliable, reproducible”, and has the potential to reduce treatment costs, office visits, and the number of medications. Furthermore, HBPM independently predicts cardiovascular morbidity and mortality.

To date, it is unknown whether physicians can target HBPM for hypertension treatment. Few studies have examined the use of medication intensification guided by HBPM. However, the current clinical standard of OBPM is less likely related to target organ damage and may have less prospective value than HBPM. This review summarizes available data to answer the following question: “How does HBPM compare with ABPM as a measurement standard for determining BP control and patient outcomes?”

Methods
Eligibility criteria
Included studies contained both HBPM and ABPM as well as any of the following outcomes, BP control, myocardial infarction, diabetes mellitus, chronic kidney disease (CKD), stroke, or all-cause mortality. Study selection was limited to the adult population, >18 years of age. Exclusion criteria included: non-English language, BP monitor validation trials, untreated hypertension, or study size <50 participants. In addition, simple correlation studies between ABPM and HBPM were excluded. We were careful not to include duplicate data that were presented in different articles. Race was frequently left out of the demographics. Very few studies reported participant income and education level for results coding.

Search strategy
Literature searches were performed by a librarian in four databases during March–April 2014: PubMed, CINAHL (EBSCO), Scopus, and Cochrane Central (Wiley). The following databases (all years) were searched: PubMed, CINAHL (EBSCO), Scopus, and Cochrane Central Register of Controlled Trials (Wiley). Searches were constructed using subject headings when available keyword synonyms to include word variations and spellings. Searches took the following form, modified for each database: (Blood Pressure Determination [MH:NoExp] OR Blood pressure OR BP [Text Word]) AND (determination [Text Word] OR monitor* OR measurement [Text Word])) AND (home OR HBP OR self [text word] OR Self Care [MH] OR telemedicine OR telemonitor* OR telemonitor OR HBPM [Text Word] OR SBPM [Text Word] AND ((Blood pressure OR BP [Text Word] OR ABP) AND (determination [Text Word] OR monitor* OR measurement [Text Word])) AND (24hour OR 24-hour OR 24 hour OR “24h” OR “24hr” OR “24hr” OR ambulatory blood pressure monitoring [Text Word] OR blood pressure monitoring, ambulatory [MeSH Terms] OR ABPM [Text Word]) AND (“clinical trial” [Publication Type] OR “clinical trial” [All Fields] OR “comparative study” [Publication Type] OR “comparative study” [All Fields] OR “retrospective studies” [MeSH Terms] OR “retrospective studies” [All Fields] OR “case–control studies” [MeSH Terms] OR “case–control studies” [All Fields] OR “follow-up studies” [MeSH Terms] OR “follow-up studies” [All Fields]).

Selection of studies
Two reviewers (TLBS and EJ) independently reviewed the titles and abstracts of the articles identified by the search strategy for potential relevance to the research question. A total of 2,714 titles and abstracts were identified of which 1,742 were screened after 972 duplicates were removed. Following this process, 137 potentially eligible full-text articles were reviewed, from which 2 reviewers identified 19 articles for inclusion in the paper. We synthesized these studies qualitatively (Figure 1).

Data management and extraction
Two reviewers (TLB-S and EJ) conducted the data extraction from papers selected to be included. The following data were extracted: participants, study design, study purpose, intervention, primary and secondary outcomes, and methodological quality. Differences in data extraction were resolved by consensus. Data extraction form was with explicit instructions that was created prior to the article review to ensure that both reviewers complete the form consistently. An evidence table was created to display the systematic overview of all studies lining up relevant data.

Assessment of methodological quality
The Jaded scale was used as a means of assessing the research methodology and scientific merit of randomized control trials. The Jaded scale is a validated scale that measures
study quality by assigning a numeric score ranging from 1 to 5 based on methodological indicators such as randomization, double blinding, and descriptions of participant dropout data.\textsuperscript{21} Observational studies were assessed using Newcastle–Ottawa Scales.

**Data synthesis**

Relevant data were synthesized qualitatively to combine the results and to draw conclusions from the findings. Data limitations prevented subgroup analyses. Subgroup analyses were not performed due to a limited number of studies with identical or similar outcomes.

**Results**

**Study characteristics**

From the search, 19 studies were included in this systematic review. Studies were grouped into three main categories by study outcome: mortality, target organ damage, and BP control (Table 1). Five studies investigated associations between BP measurement type (eg, OBPM, HBPM, and ABPM) and mortality. These studies consisted of observational analyses in distinct populations, including patients with CKD or end-stage kidney disease in the United States,\textsuperscript{22,23} patients \( \geq 60 \) years of age from a single primary care practice in Belgium,\textsuperscript{24} and the general populations in Japan\textsuperscript{25} and Italy.\textsuperscript{26} Sample sizes ranged from 210 to 2,051 participants with median follow-up times between 2.4 and 12.3 years (Table 1).

Four studies compared target organ damage between the different BP measurement types. Target organ damage was measured as urine albumin-to-creatinine ratio, left ventricular hypertrophy by either electrocardiogram or echocardiogram, pulse wave velocity, or flow-mediated dilation of the brachial artery. Two studies were cross-sectional analyses with a single time point of data collection,\textsuperscript{27,28} and two were prospective designs with follow-up times of 6 and 12 months.\textsuperscript{18,25} Sample sizes ranged from 59 to 854 participants (Table 1).

The remaining ten studies contained all three types of BP measurement (OBPM, HBPM, and ABPM) and BP control data. Two were cross-sectional observational analyses,\textsuperscript{30,31} five were randomized controlled trials,\textsuperscript{32–36} and three were quasi-experimental studies without an active intervention\textsuperscript{37,38} or a control group.\textsuperscript{39} The majority of study populations consisted of individuals with mild-to-moderate hypertension, either treated or untreated. Trials were short in length ranging from 4 weeks to 6 months. Antihypertensive medication formed the intervention for three of the five randomized controlled trials. Two trials randomized participants to have their BP medication adjusted according to HBPM vs OBPM\textsuperscript{33} or HBPM vs ABPM.\textsuperscript{36}

**Study findings**

The major findings of each study are summarized in Table 1. Associations between BP measurement type (eg, OBPM, HBPM, and ABPM) and mortality differ by study population. In patients with CKD or end-stage kidney disease, ABPM is a superior predictor of mortality.\textsuperscript{22,23} For persons \( \geq 60 \) years of age, HBPM is as good or better than ABPM when predicting mortality in older patients.\textsuperscript{24} In the general population, additional BP information regardless of measurement type (OBPM, HBPM, and ABPM) contributes to cardiovascular risk.\textsuperscript{26} However, only BP assessed by HBPM and ABPM is associated with all-cause mortality.\textsuperscript{25}

Data describing associations between BP measurement type and target organ damage are limited with only four studies meeting inclusion criteria. In general, arterial stiffness (measured by pulse wave velocity), albuminuria, and left ventricular mass were associated with changes in BP regardless of measurement type.\textsuperscript{18,28}

Regarding BP control, benefits emerge when including HBPM. In patients receiving hemodialysis, targeting antihypertensive treatment to home BPs as opposed to predialysis BPs results in better BP control, as assessed by ABPM.\textsuperscript{33} Fuchs et al showed that merely randomizing an individual to HBPM and not making any antihypertensive medication adjustments improves BP control.\textsuperscript{38} Using HBPM to titrate antihypertensive medication produces the same level of control as using ABPM.\textsuperscript{36}

Targeting OBPM for control is limited by the low sensitivity of office BP to detect optimal BP control defined by
either HBPM or ABPM (50% and 53.4%, respectively). Many studies agree that the correlation between HBPM and ABPM is stronger than that of OBPM with ABPM. However, in the general hypertensive population, HBPM can result in fewer prescribed medications with less BP control.

### Discussion
The systematic selection of studies containing both HBPM and ABPM produced only 19 unique studies with a combined number of study participants near 7,100. Data were too limited to determine the benefit of using HBPM as a BP target when adjusting antihypertensive medications. This lack of data in the highly studied hypertensive population is a major finding in and of itself. However, clinically relevant conclusions can still be drawn from our review.

All of the studies that evaluated the relationship between OBPM, HBPM, and ABPM found HBPM to be correlated with ABPM and this correlation was stronger than that of OBPM and ABPM. This agreement in combination with the
low sensitivity of office BP to detect optimal BP control by ABPM and the added association of HBPM with cardiovascular mortality all support the use of HBPM when treating hypertension. It is not surprising that routine use of HBPM has been recommend for almost a decade. Currently, the American Heart Association, the American Society of Hypertension, and the Preventive Cardiovascular Nurses Association suggest that HBPM be incorporated into usual care.

By comparison, HBPM has some advantages over ABPM. The availability of affordable BP monitoring devices has allowed individuals to measure and record BPs repeatedly throughout their course of treatment. In contrast, ABPM is not directly available to patients, and its high cost presents a barrier to initial and repeated testing. By requiring the individual to wear the cuff and monitor continuously, ABPM does interfere with daily activities and sleep. Although, any advantage in convenience or comfort with HBPM is weighed against the superior standardization of BP measurement and the acquisition of sleep-time BP data by 24-hour ABPM.
It is important to note that large randomized trials investigating hypertension treatment have targeted BP measured during study visits, similar to OBPM, when evaluating medication efficacy and participant outcomes. For this reason, HBPM should not supplant OBPM. While the addition of HBPM will help physicians to identify patients with masked-uncontrolled hypertension (ie, individuals controlled in the office yet uncontrolled at home), in patients with low home BPs, HBPM data can adversely affect treatment decisions. The study by Bailey et al offers a reminder to physicians that care must be taken when incorporating HBPM data into treatment strategies. Physician behavior was influenced by HBPM readings and resulted in fewer prescribed medications; systolic BP by 24-hour ABPM was 137±3 mmHg for the group randomized to HBPM compared with 130±3 mmHg in the usual care group.37

However, HBPM can improve BP control through its indirect effects on patients. HBPM encourages patient-centered care. Self-monitoring of BP reminds patients of the importance of medication adherence and healthy lifestyle factors. The study by Fuchs et al supports these indirect effects of self-monitoring. Participating in HBPM alone improved BP control.38

Limitations
In the review process, we identified numerous studies with both HBPM and ABPM data that were designed as validation studies for BP monitoring devices. While these studies do contain information regarding BP control, they did not align with our interpretation of the outcome of BP control. Variability existed in the timing of HBPM both in the length of monitoring time (2–14 days) and in the frequency of measurement (two to six times per day). On the other hand, ABPM was more consistent with measurements every 15–20 minutes while awake and 15–30 minutes while asleep for a total of 24–44 hours.

An important distinction between HBPM and ABPM is the inclusion of nocturnal measurements with ABPM. We did not pursue outcome associations with isolated nocturnal hypertension. Furthermore, this study examined the effect of BP measurement type on BP control and clinical outcomes, yet did not attempt to answer the question of what is the goal BP.

Conclusion
Our findings support the guideline recommendations to include HBPM in the management of hypertension. The benefits of identifying masked-uncontrolled hypertension and increasing patient participation in his/her care outweigh the risk of undertreating patients with white coat phenomena.
