Abstract: This paper reviews state-of-the-art microwave ablation (MWA) of tumors. MWA is a novel method for treating inoperable tumors, ie, tumors that cannot be treated surgically. However, patients generally choose removal of the tumor by conventional techniques. A literature review of MWA for breast, liver, lung, and kidney tumors is reported here, with tabulation of our findings according to the type of technique used, with a detailed description of the time, type of microwave generator used, and number of patients treated with MWA. In some cases, the subjects were not human patients, but pig or bovine liver specimens. MWA is a technique that has proved to be promising and likely to be used increasingly in the ablation of cancerous tumors. However, MWA needs to be used more widely to establish itself as a common tool in the treatment of inoperable tumors.

Keywords: tumor, ablation, microwave, review

Introduction

A tumor is a swelling of a part of the body, generally without inflammation, caused by an abnormal growth of tissue, whether benign or malignant. Tumors can be cancerous (malignant) or non-cancerous (benign), and occur when cells multiply excessively in the body. Normally, the division and growth of cells occurs in a controlled manner. New cells are created all the time to replace old ones or to perform new functions. Cells that are damaged or are no longer needed die off and are replaced with fresh cells. If the balance of division and cell death is altered, a tumor may appear.

According to 2012 World Health Organization statistics, the most frequent types of cancer worldwide (ranked according to number of deaths globally) are of the lung, prostate, colon, rectum, stomach, and liver (in men), and breast, colon, rectum, lung, cervix, and stomach (in women). There are several methods available to treat cancerous tumors, the most common being surgery, radiotherapy, and systemic chemotherapy.

With early detection of tumors, it is possible to use a minimally invasive new technique that works by increasing the temperature inside the tumor hyperthermia, while avoiding damage to healthy adjacent tissue.

Tumor ablation

Placement of a needle or catheter directly into a tumor and the use of heat, cold, or a chemical to destroy it is known as ablation. It is used most frequently to stop the spread of cancer to the bones or liver, although it can also be used in other organs. Ablation is usually employed when only a limited number of tumors are causing problems.

A common type of ablation, ie, radiofrequency ablation, uses a needle that carries an electric current. The end of the needle is placed into the tumor. Ultrasound or computed tomography can be used to ensure that the needle is correctly positioned. An electrical
current is then passed through the needle, heating the tumor and destroying it. In general, radiofrequency ablation is done while the patient is under general anesthesia. Another type of ablation, known as cryoablation, uses a probe placed inside the tumor to freeze it, which destroys cancer cells. Other methods use heat (laser-induced interstitial thermotherapy) or alcohol to destroy cells.

### Microwave tumor ablation

Microwaves are being used increasingly in medicine for ablation of tumors, causing them to be burned and destroyed. Several prototype antennae have been used to perform microwave ablation (MWA). These antennae are designed to be as small as possible and with increasingly precise targeting power to prevent damage to healthy tissue.

The expectations generated by MWA have also sparked other investigations. Researchers are developing such antennae to generate heat via microwaves, as show in figure 1, and more patents are being granted for different antenna designs. The development of new software tools and other advances have led to the appearance of new methods for application of microwaves to ablate tumors. The figure 2 show the simulation of Microwave applicator inserted in breast tissue. Many research groups are investigating the effectiveness of MWA in the treatment of cancer. As they progress, there are more studies published on the evaluation, the comparison to other techniques and the application of ablation using microwaves. The tables included in this paper show the main features of some of the studies published in recent years.

</tr>
</tbody>
</table>

Abbreviation: MWA, microwave ablation.
in 60 patients with 96 tumors measuring 1–8 cm, complete ablation was observed in 89 tumors.7

The conclusion of Tables 3 and 4 is similar to that for liver tumors, ie, MWA is a viable treatment option for lung and kidney tumors, with results similar to those of surgery when patients are followed up at 1, 3, and 6 months for lung and kidney tumors, and complete necrosis were seen in most patients.

There are presently no data available on the use of MWA in breast cancer. However, in 2011, Cepeda suggested using MWA for this type of cancer. Figure 3 shows the injury caused by the applicator, which was used in the ex vivo test. In his doctoral thesis, he elaborated the design of an applicator for minimally invasive MWA, performing a computational analysis by finite element modeling, and then validated the model with experiments on phantoms and ex vivo porcine tissue breast.49

**Conclusion**

MWA has proven to be a successful therapeutic tool in the treatment of cancer. Its use is expected to increase in frequency for ablation of tumors. Although many successful tests have been done, MWA has not progressed to widespread use in dedicated cancer treatment centers, in particular for inoperable tumors (even though most of the clinical studies have been done in people who could not be treated by surgery). The advantages of MWA need to be recognized more widely, given that it has been proven to be effective. Hospitals should consider acquiring the expertise and infrastructure needed to establish MWA for the treatment of cancers, and thus offer patients an alternative treatment option.
