Abstract: The stereoselective synthesis of lippialactone was achieved in high overall yield from commercially available D-mannitol. Key reactions involved in the synthesis are preparation of required epoxide (**5**), its opening with vinyl Grignard reagent, and olefin cross-metathesis. A new route to a vinyl lactone (**4**) was explored.

Keywords: D-mannitol, epoxide, vinyl Grignard, cross-metathesis

Introduction

Natural products possessing the 5,6-dihydro-2-pyrone (α -pyrone) subunit as a core structure, bearing on position 6 an additional alkenyl chain, are known to display a broad spectrum of pharmacological properties,¹⁻⁴ such as insect growth inhibition, and antimicrobial, cytotoxic, and antitumoral activities. In 2013, Ludere et al⁵ isolated a new antimalarial agent, lippialactone (**1**) (Figure 1), from aerial parts of *Lippia javanica*. Lippialactone is active against the chloroquine-sensitive D10 strain of *Plasmodium falciparum*, with a half maximal inhibitory concentration (IC_{50}) value of 9.1 μ g/mL, and is known to show mild cytotoxicity. The relative stereochemistry of lippialactone was determined by molecular modeling based on the determination of the relative configuration, by quantum mechanical gauge including atomic orbitals (GIAO) ^{13}C chemical-shift calculations. Lippialactone (**1**) is structurally related to synargentolide A (**2**) (Figure 1), whose structure was revised by our team.⁶ To date, however, only a single report has appeared on the synthesis of **1**.⁷ In continuation of our interest in the synthesis of bioactive natural δ -lactones,⁸⁻¹⁴ we herein describe a stereoselective total synthesis of lippialactone.

Experimental General

Reactions were conducted under N_2 , in anhydrous solvents such as CH_2Cl_2 , tetrahydrofuran (THF), and ethyl acetate (EtOAc). All reactions were monitored by thin-layer chromatography (TLC) (silica-coated plates and visualization under ultraviolet [UV] light). *n*-Hexane (bp 60°C–80°C) was used. Yields refer to chromatographically and spectroscopically (1H and ^{13}C nuclear magnetic resonance [NMR]) homogeneous material. Air-sensitive reagents were transferred by syringe or double-ended needle. Evaporation of solvents was performed at reduced pressure on a BÜCHI rotary evaporator (BÜCHI Labortechnik AG, Flawil, Switzerland). 1H and ^{13}C NMR spectra of samples in $CDCl_3$ were recorded on Varian FT-400MHz (Varian Medical Systems Inc.,

Mass spectra recorded E1 conditions at 70 eV on ES-MSD (Agilent Technologies, Santa Clara, CA, USA) spectrometers. Column chromatography was performed on silica gel (60–120 mesh) supplied by Acme Chemical Co, India. TLC was performed on Merck 60 F-254 silica gel plates (Merck KGaA, Darmstadt, Germany). Optical rotations were measured with a JASCO DIP-370 Polarimeter (JASCO Corp, Tokyo, Japan).

The reaction mixture was stirred at room temperature (RT) for 1 hour. It was then diluted with water and extracted with CH_2Cl_2 . The organic layer was washed with brine and dried over anhydrous Na_2SO_4 . Removal of solvent under reduced pressure afforded the unstable crude tosyl compound **7**, which was used for further reaction. To a stirred suspension of LiAlH_4 (0.49 g, 12.89 mmol), in dry THF (10 mL) at 0°C, was added dropwise a solution of compound **7** (2.5 g, 6.47 mmol) in dry THF (10 mL). The reaction mixture was refluxed for 3 hours. It was then cooled to 0°C, diluted with Et_2O , and quenched by the dropwise addition of saturated aqueous Na_2SO_4 . The solid material was filtered and washed thoroughly with hot EtOAc several times. The combined organic layers were dried over anhydrous Na_2SO_4 . To an ice-cooled solution of 2-(iodooxy) benzoic acid (0.32 g, 1.17 mmol) in anhydrous CH_3CN (7 mL) was added a solution of alcohol **16** (0.100 g, 0.78 mmol). The mixture was refluxed for 1 hour and then allowed to cool to RT. The solvent was removed under reduced pressure, and the unstable crude aldehyde product was used directly for the next step without further purification by column chromatography.

In a reaction flask, a 2.5 M solution of *n*-BuLi in hexane (0.9 mL, 2.28 mmol) was added under N_2 atmosphere to a

Results and discussion

The retrosynthetic analysis of lippialactone (**1**) is summarized in Figure 2. Lippialactone (**1**) could be accomplished from homoallyl alcohol **3** and vinyl lactone **4** via an olefin cross-metathesis reaction. In turn, the construction of three contiguous stereogenic hydroxyl groups in compound **3** could be achieved from commercially available D-mannitol, and vinyl lactone **4** could be prepared from a known chiral epoxide **12**¹⁵ by a new synthetic route.

The synthesis of fragment **3** (Figure 3) commenced from a primary alcohol **6**, which was prepared from D-mannitol^{16,17} according to the reported procedure. Tosylation of the primary hydroxyl group in compound **6**, with TsCl, Et₃N, and DMAP in CH₂Cl₂, gave compound **7**, which on treatment with lithium aluminum hydride (LAH) gave a terminal methyl compound **8**. Selective deprotection of the terminal acetonide with

CuCl₂·2H₂O in CH₃CN afforded diol **9**. Selective protection of the primary hydroxy group in **9**, as the pivaloyl ester, with PivCl, Et₃N, and DMAP in dichloromethane (DCM) gave compound **10**. Mesylation of the secondary hydroxyl group in compound **10**, with MsCl, Et₃N, and DMAP in CH₂Cl₂, gave secondary mesylate. This was followed by the treatment with anhydrous K₂CO₃ in anhydrous MeOH, at RT, which afforded epoxide **5** with the required stereocenter. Opening of epoxide **5** with vinylmagnesium bromide in the presence of CuI afforded homoallyl alcohol **11**. The resulting free secondary hydroxyl group was acetylated to give a mono-acetate compound **3**.

The other fragment, vinyl lactone **4**, was prepared from a known epoxide **12**¹⁵ as shown in Figure 4. The epoxide was subjected to regioselective ring opening with propargyl alcohol using LiHMDS, then BF₃·OEt₂ at -78°C to furnish alcohol **13**, in 85% yield. The triple bond in **13** was reduced to a Z-double bond using Lindlar catalyst to afford **14**, in 90% yield. Oxidative cyclization of 1,5-diol **14** with TEMPO and [bis(acetoxy)iodo]benzene [(PhI(OAc)₂] (BAIB)¹⁸ produced the desired δ-lactone **15**, in 90% yield.

Oxidative removal of the 4-methoxybenzyl ether (PMB) group (DDQ/CH₂Cl₂:H₂O, 9:1, 0°C-rt, 92%) and oxidation of the resulting alcohol **16** to the corresponding aldehyde, and subsequent treatment with one carbon Wittig reagent furnished vinyl lactone **4** ((a) IBX/CH₃CN, b) PPh₃=CH₂, THF, 0°C-rt, 75% over two steps).

With the two key fragments in hand, the CM reaction was planned. Olefin cross-metathesis¹⁹⁻²¹ between fragment **3** and vinyl lactone **4** was promoted smoothly by the second-generation Grubb's catalyst in CH₂Cl₂ under reflux, to yield the desired lactone **17** (82%) exclusively (Figure 5).

Finally deprotection of acetonide group in compound **17**, followed by acetylation of the resulting diol **18** produced the target molecule, lippialactone (**1**). The spectroscopic and

analytical data of the synthetic compound are in good agreement with those reported for the natural product.

Conclusion

In conclusion, the stereoselective synthesis of lippialactone from D-mannitol has been achieved. Vinyl lactone used in the present synthesis was prepared by a new synthetic route. LAH reduction, epoxide opening, and olefin cross-metathesis reactions were used as key steps.
