Abstract: FHIT is a bona fide tumor-suppressor gene and its loss contributes to tumorigenesis of epithelial cancers including breast cancer (BC). However, the association and clinicopathological significance between FHIT promoter hypermethylation and BC remains unclear. The purpose of this study is to conduct a meta-analysis and literature review to investigate the clinicopathological significance of FHIT methylation in BC. A detailed literature search was performed in PubMed, EMBASE, Web of Science, and Google Scholar databases. The data were extracted and assessed by two reviewers independently. Odds ratios with 95% corresponding confidence intervals were calculated. A total of seven relevant articles were available for meta-analysis, which included 985 patients. The frequency of FHIT hypermethylation was significantly increased in invasive ductal carcinoma compared to benign breast disease, the pooled odds ratio was 8.43, \( P<0.00001 \). The rate of FHIT hypermethylation was not significantly different between stage I/II and stage III/IV, odds ratio was 2.98, \( P=0.06 \). In addition, FHIT hypermethylation was not significantly associated with ER and PR status. FHIT hypermethylation was not significantly correlated with premenopausal and postmenopausal patients with invasive ductal carcinoma. In summary, our meta-analysis indicated that the frequency of FHIT hypermethylation was significantly increased in BC compared to benign breast disease. The rate of FHIT hypermethylation in advanced stages of BC was higher than in earlier stages; however, the difference was not statistically significant. Our data suggested that FHIT methylation could be a diagnostic biomarker of BC carcinogenesis. FHIT is a potential drug target for development of demethylation treatment for patients with BC.

Keywords: FHIT, methylation, tumor suppressor gene, meta-analysis, odds ratio, drug target

Introduction

Breast cancer (BC) is the most frequently diagnosed cancer in women and the major cause of cancer-related female mortality in the USA. A series of epigenetic alterations and genetic abnormalities contribute to this process of BC onset and progression. Epigenetic alterations, which occur in transformed cells, involve changes in DNA methylation, including global hypomethylation, focal hypermethylation, histone modifications, and nucleosomal remodeling. Specifically, abnormal promoter region methylation in tumor suppressor genes results in loss of gene function which contributes to tumorigenesis of epithelial cancers. Therefore, it is critical to identify biomarkers for diagnosis and new molecular targets for development of personalized therapy. Common fragile sites are large chromosomal regions that are hot spots for alterations, especially in cancer cells. The three most frequently expressed common fragile site regions are FRA3B, FRA16D, and FRA6E which contain FHIT, WWOX, and PARK2.
The FHIT gene is a bona fide tumor-suppressor gene present on the short arm of chromosome 3 and its loss of function has been evaluated in different types of cancers including BC.\(^5\)\(^,\)\(^7\) FHIT plays an important role in pro-apoptotic signaling, cell cycle control, and sensitivity to DNA damaging agents.\(^8\)\(^-\)\(^10\) Viral-mediated FHIT gene transfer to FHIT-deficient mice not only prevents but reverses the carcinogen-induced tumor development in vivo and restoration of FHIT protein induces tumor suppression in 50% of tumor cell lines tested in vitro.\(^11\) However, the association and clinical significance between FHIT promoter hypermethylation and BC remains under investigation. In this study, we systematically reviewed studies of FHIT promoter hypermethylation in this process of BC onset and progression, and quantified the association between FHIT promoter hypermethylation and BC by using meta-analysis methods. In addition, we summarize these findings and discuss the tumor suppressor function, as well as the clinical significance of FHIT in BC.

**Materials and methods**

**Search strategy and selection criteria**

We performed comprehensive literature searches in PubMed, EMBASE, Web of Science, and Google Scholar databases in May 2015 with no limit set for date and language of publication using the search terms: “breast cancer or breast carcinoma”, “methylation”, and “FHIT, or Fragile histidine triad”. There were 103 articles identified from PubMed, 30 articles from EMBASE, 85 articles from Web of Science, and 16,600 articles from Google Scholar, first 400 of them were screened because the rest of them were not related to the present study. A total of 618 articles were screened by article titles and abstracts.

After screening by titles and abstracts, individual studies were screened using the inclusion and exclusion criteria. We included studies that met the following criteria: 1) studies that evaluated FHIT hypermethylation in the primary BC tissues, 2) research that revealed the relationship between FHIT hypermethylation and BC clinicopathological parameters, 3) FHIT hypermethylation examined by polymerase chain reaction. The exclusion criteria included the following: 1) reviews, case reports, letters, editorials, expert opinion, conference abstracts and 2) all studies using cell lines serum, human xenografts, and in vitro/ex vivo studies were also excluded. The search process was conducted independently by two reviewers (XW and JL), discrepancies were discussed and resolved by the third reviewer (JX). Forward and backward citation chasing of each included article was conducted. The most complete study was chosen to avoid duplication if the same patient populations were reported in several publications. Seven articles were eligible for inclusion in this meta-analysis.

**Data extraction and methodological assessment**

Two authors (YS, XW) independently reviewed and extracted the following data: last name of the first author, year of publication, country(ies) where the study was conducted, number of BC cases, clinicopathological parameters, cancer tumor-node-metastasis stage, methylation detection method, methylation rate and/or expression. The detailed information of seven relevant articles is listed in Table 1.

**Abbreviations:** BC, breast cancer; mRNA, messenger RNA; MSP, methylation-specific polymerase chain reaction; PCR-SSCP, polymerase chain reaction single-strand conformation polymorphism; RT-PCR, reverse transcription polymerase chain reaction; ER, estrogen receptor; PR, progesterone receptor.
Heterogeneity of investigation was evaluated to determine whether or not the data of various studies could be analyzed for a meta-analysis.

For the methodological evaluation of the studies, three investigators (JL, XW, and JX) read through each publication independently, and they assessed and scored them according to the Reporting Recommendations for Tumor Marker Prognostic Studies guidelines and European Lung Cancer Working Party quality scale. Three readers provided the quality scores and compared them, and then reached a consensus value for each item.

Statistical analysis

Analysis was conducted using Review Manager 5.2 (Cochrane Collaboration, Oxford, UK). The pooled odds ratios (ORs) with its 95% confidence intervals (CIs) were calculated. Heterogeneity among studies was estimated using the Cochran’s Q statistic and F tests. The F statistics were used to examine the difference for between-study variability due to heterogeneity rather than chance, with a range from 0% to 100%. When heterogeneity (F) was less than 50%, a fixed effect model was used to calculate parameters. If there was substantial heterogeneity (F values ≥50%), a random-effects model was used to pool data and attempt to identify potential sources of heterogeneity based on subgroup analyses. The analysis was performed to compare the frequency of FHIT methylation between BC and nonmalignant breast tissue. The frequency of FHIT hypermethylation was compared in different tumor characteristics. The pooled ORs were estimated for the correlation between FHIT hypermethylation and clinicopathological features. P-values tailed less than 0.05 were considered statistically significant. Publication bias is what occurs whenever the research in the published literature is systematically unrepresentative of population of completed studies. Funnel plots were used for detection of publication bias.

Results

Identification of relevant studies

The initial database search resulted in a total of 618 citations. After review, seven articles were included for meta-analysis, as shown in Figure 1.

Study characteristics

Seven studies published from 2001 to 2011 were eligible for meta-analysis. A total of 985 BC patients from India, People’s Republic of China, Japan, Egypt, and the USA were enrolled. Their basic characteristics are summarized in Table 1.
Figure 2 Forest plot for FHIT hypermethylation in IDC and benign breast disease.

Abbreviations: IDC, invasive ductal carcinoma; df, degrees of freedom; CI, confidence interval; M–H, Mantel–Haenszel.

Figure 3 Forest plot for FHIT hypermethylation in different stages of BC.

Abbreviations: BC, breast cancer; CI, confidence interval; df, degrees of freedom; M–H, Mantel–Haenszel.

Figure 4 Forest plot for FHIT hypermethylation in ER-positive and -negative BC.

Abbreviations: BC, breast cancer; CI, confidence interval; df, degrees of freedom; M–H, Mantel–Haenszel; ER, estrogen receptor.

Figure 5 Forest plot for FHIT hypermethylation in PR-positive and -negative BC.

Abbreviations: BC, breast cancer; CI, confidence interval; df, degrees of freedom; M–H, Mantel–Haenszel; PR, progesterone receptor.
studies, four scored eight points, two scored seven points, and one scored six points. Hence, the studies were of a relatively high quality (data not shown). A sensitivity analysis was conducted by removing one study from the meta-analysis at a time; the overall results were not significantly affected. The pooled ORs were not significantly changed, indicating the stability of our analyses. The funnel plots were largely symmetric (Figure 7A–E), suggesting there were no publication biases in the meta-analysis of FHIT hypermethylation and clinicopathological features.

**Discussion**

Aberrant DNA methylation has been recognized to contribute to breast carcinogenesis, and promoter hypermethylation of several tumor suppressor genes including APC, GSTP1, P14 (ARF), P16 (CDKN2A), P21 (CDKN1A), PTEN, and TIMP3 has been correlated with decreased gene expression.\(^{5,15-17}\) FHIT gene, encompassing the FRA3B fragile site at chromosome 3p14.2, is a putative tumor suppressor gene involved in the pathogenesis of different tumor types including BC.\(^{18,19}\) FHIT messenger RNA (mRNA) is expressed in most normal human tissue, with highest level in epithelial cells.\(^{20}\) The FHIT gene is inactivated by genetic and epigenetic changes, ie, loss of heterozygosity or promoter hypermethylation, in numerous cancers.\(^{21}\) Originally, the absence of FHIT protein in tumors was examined as a loss of heterozygosity, mainly due to biallelic deletions of the gene. Recent evidence indicates that inactivation of FHIT...
by promoter hypermethylation plays an important role in tumorigenesis in several types of tumors including BC.\(^{22-27}\) However, the reported correlation between \(FHIT\) methylation and clinicopathological features in BC was inconsistent. We conducted the meta-analysis to determine the association between \(FHIT\) hypermethylation and clinicopathological characteristics in BC.

Our data revealed that the frequency of \(FHIT\) hypermethylation in BC was 8.43 times higher than that in benign breast tissues. Haroun et al observed that the methylation frequencies of the genes tested in non-small cell lung carcinoma specimens were 53.6% for \(FHIT\).\(^{28}\) Jeong et al evaluated the methylation of \(FHIT\) in 60 BC samples; \(FHIT\) methylation was detected in 96.7% and the positive expression rate of \(FHIT\) in 87.3% of the patients.\(^{27}\) Our data and previous studies indicate that \(FHIT\) promoter hypermethylation is a useful diagnostic biomarker of BC. \(FHIT\) promoter hypermethylation is reversible, drug treatment through demethylation may be useful to delay tumorigenesis and progression, as well as improving prognosis. Inhibitors of DNA methylation such as 5-Aza-CdR and FdCyd were applied to human BC cells and induced apoptosis,\(^{16,28}\) and FdCyd is now in clinical trials for the treatment of BC and other solid tumors.\(^{29-31}\) More specifically, Stewart et al observed that there was a statistically significant increase in expression of \(FHIT\) as well as two other tumor suppressor genes, \(FUS1\) and \(WWOX\), in patients with tumor regression following decitabine, which is a demethylating agent.\(^{19}\) These preclinical studies and early clinical trials showed the potential to restore the activity of epigenetically silenced \(FHIT\) through epigenetic modulating agents and promise of reexpressed tumor suppressors as markers and effectors of responses. This approach provides a promising drug target for development of personalized therapy of BC in the future.

Our data showed the nonsignificant association of \(FHIT\) hypermethylation with ER, PR, and menopausal status of BC patients. Those data were different from previous studies which reported significant associations between \(FHIT\) hypermethylation and ER-negative as well as in PR-negative cases. Since the power of our analysis is small, further evaluation needs to be carried out in a larger sample study. Sensitivity analysis showed that no individual study significantly biased the pooled result and no evidence of publication bias was found. There are several potential limitations: 1) the search strategy was restricted to articles published in English and Chinese, some studies published in other languages were not included in current study; 2) the possibility of information and selection biases as well as unidentified confounders could not be completely excluded because all of the included studies were observational. Therefore, caution should be exercised when our findings are interpreted among the general population.

In conclusion, our meta-analysis indicated that the frequency of \(FHIT\) hypermethylation was significantly increased in BC compared to benign breast disease. Our data suggested \(FHIT\) could be a diagnostic biomarker. In addition, \(FHIT\) is a potential drug target for development of demethylation treatment for patients with BC.

Drug Design, Development and Therapy

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
