Biosynthesis characterization of silver nanoparticles using *Cassia roxburghii* DC. aqueous extract, and coated on cotton cloth for effective antibacterial activity

**Abstract:** The present study reports the green synthesis of silver nanoparticles (AgNPs) from silver precursor using a plant biomaterial, *Cassia roxburghii* DC., aqueous extract. The AgNPs were synthesized from the shade-dried leaf extract and assessed for their stability; they elucidated characteristics under UV–visible spectroscopy, X-ray diffraction, Fourier transform infrared spectroscopy, high-resolution transmission electron microscopy, and energy dispersive X-ray spectroscopy. The synthesized AgNPs exhibited a maximum absorption at 430 nm, and the X-ray diffraction patterns showed that they were crystal in nature. Fourier transform infrared spectroscopy analysis confirmed the conversion of Ag⁺ ions to AgNPs due to the reduction by capping material of plant extract. The HR-TEM analysis revealed that they are spherical ranging from 10 nm to 30 nm. The spot EDAX analysis showed the presence of silver atoms. In addition, AgNPs were evaluated for their antibacterial activity against six different pathogenic bacteria: three Gram-positive bacteria, *Bacillus subtilis*, *Staphylococcus aureus*, and *Micrococcus luteus*, and three Gram-negative bacteria, *Escherichia coli*, *Pseudomonas aeruginosa*, and *Enterobacter aerogenes*. They were highly sensitive to AgNPs, whereas less sensitive to AgNO₃. Furthermore, the green synthesized AgNPs were immobilized on cotton fabrics and screened for antibacterial activity. The immobilized AgNPs on cotton cloth showed high antibacterial activity. Therefore, they could be a feasible alternative source in treating wounds or may help in replacing pharmaceutical band-aids.

**Keywords:** bioreduction, stability, immobilization, cotton cloth, minimum inhibitory concentration

**Introduction**

Nanomaterials are at the leading edge of the rapidly developing field in nanotechnology. Their unique size makes them superior and indispensable in many areas of human activity. Nanotechnology encompasses the production and application of physical, chemical, and biological systems at scales ranging from individual atoms or molecules to submicron dimensions, as well as the integration of the resulting nanostructures into larger systems. Science and technology research in nanotechnology promises breakthroughs in areas such as materials and manufacturing, nanoelectronics, medicine and health care, energy, biotechnology, and information technology. Nanoparticles are usually referred to as the particles with a maximum size of 100 nm. Nanoparticles exhibit new properties when compared to larger particles of the bulk material. The novel properties are derived due to the variations in specific characteristics, such as size, distribution, and morphology of particles. The nanoparticles have a wide range of applications, such as in combating microbes, drug delivery, catalysis, water purification, and treatment of wounds or may help in replacing pharmaceutical band-aids.
of environmental waste, food industry, textile industry, biolabeling, and treatment of cancer.

Generally, metal nanoparticles can be prepared and stabilized by physical and chemical methods. The chemical approaches, such as chemical reduction, electrochemical techniques, lithography, and photochemical reduction, are most widely used. Though they have the control over the size and shape of the nanoparticles, they pose some threats when they are being used in the medical applications. Moreover, they are expensive, need high pressure, energy, and temperature, and need use of some toxic chemicals for the stabilization of nanoparticles, leading to adverse effects when they are being applied in the medical and pharmaceutical applications; hence, there is an increasing need for the development of an eco-friendly process for the synthesis of nanoparticles. Plants have attracted more attention than the bacteria and fungi as they are easily available and do not require the maintenance of highly aseptic conditions. Among the noble metal nanoparticles, silver nanoparticles (AgNPs) are considered to be of great importance because of their high antiviral, antibacterial, and antifungal properties and good electrical conductivity, chemical stability, and catalytic activity.

Though there is a widespread use of AgNPs in the medical, cosmetics, and pharmaceutical industries, there is a threat, as to the release of nanoparticles into the environment and their interaction with the biotic components of the ecosystem. Different sizes and shapes of the nanoparticles could pose a threat to human and environmental health. Hence, proper knowledge of the engineered nanomaterials, their mode of interaction, uptake, accumulation, and impact on the biosystems at various levels is inevitable to implement proper control to avoid nanopollution turning out to be a serious ecological concern. Recently, it has been shown that different sizes of AgNPs (20–80 nm) were toxic to thale cress (Arabidopsis thaliana) seedlings and they caused stunted growth even at very low concentration. Hence, it is assumed that the toxicity induced by the AgNPs on the plant system might be due to the presence of the toxic compounds present on the surface of the nanoparticles. Cassia roxburghii DC. is a graceful tree with spreading, drooping branches appearing to be overweighted by its wealth of clustering orange–red blossoms. C. roxburghii is native to Sri Lanka and Southern India. Cassia species are widely used in folk medicine for their laxative, purgative uses, and for treating skin diseases, such as ring worm, scabies, eczema, and wounds. C. roxburghii had been used in ethnomedicine for various liver disorders for its hepatoprotective activity. It is also being used in vivo wound healing. In the present study, AgNPs were synthesized from C. roxburghii. They were characterized using high-resolution transmission electron microscopy, energy dispersive X-ray (EDX) spectroscopy, Fourier transform infrared spectroscopy (FTIR), and X-ray diffraction (XRD) analysis. The antibacterial activity of AgNPs and AgNPs coated on cotton fabric was investigated against six different pathogenic bacteria.

Materials and methods
All the analytical grade chemicals were purchased from Sigma-Aldrich Co. (St Louis, MO, USA). Silver nitrate was purchased from HiMedia Laboratories (Mumbai, India). The bacteria were obtained from the Culture Collection Facility at the Centre for Advanced Studies in Botany, University of Madras, Chennai.

Collection of plant materials
The healthy leaves of C. roxburghii were collected in and around Guindy campus, University of Madras, Chennai, during January 2012. They were washed twice with tap water and then rinsed with distilled water, removing dust particles from their surface. Then the leaves were shade dried for 3 days at room temperature.

Preparation of the plant extract
The air-dried leaves were ground to coarse powder using a blender; 4.0 g of the dried leaf powder sample was taken and mixed with 100 mL of glass distilled water. This mixture was kept at 55°C for 15 minutes in a water bath and cooled to room temperature and filtered through Whatman No 1 filter paper. This aqueous extract was refrigerated and used for further experiments.

Synthesis of AgNPs
A total of 1 mL of the C. roxburghii leaf aqueous extract was added to 9 mL of 1 mM solution of silver nitrate in a 15 mL test tube. The reaction was performed in dark at room temperature overnight to minimize photoactivation of silver nitrate. The aqueous leaf extracts of C. roxburghii and AgNO₃ solution were used as control. After the desired reaction period, the solution containing the AgNPs was centrifuged at 15,000 rpm for 10 minutes. The pellet was collected and redispersed in glass-distilled water, removing any interactive biological molecules. This was repeated thrice to ensure better separation of the AgNPs and was used for characterization studies.
Characterization of AgNPs

UV–visible spectroscopy

The formation of dark brown color during the synthesis was confirmed as the formation of AgNPs. The reduction of the pure AgNPs was recorded under UV–visible spectroscopy using Hitachi U-2900 UV–visible spectrophotometer between 300 nm and 700 nm. The UV–visible spectra of the plant leaf extract and silver nitrate solution were also recorded.

Stability of AgNPs

Time

The stability of AgNPs from C. roxburghii was recorded between 300 nm and 700 nm at different time intervals such as 0 hour, 6 hours, 12 hours, 18 hours, and 24 hours to 2 months. The absorbance of the solutions was measured using Hitachi U-2900 UV–visible spectrophotometer.

HR-TEM and EDX

A drop of AgNPs was placed on carbon-coated copper grids and allowed to stand for 2 minutes, and the excess solution was removed using a blotting paper allowed to dry at room temperature. High-resolution transmission electron microscopy observations were made on a FEI-TECNAI G2 T-30, S-Twin instrument. EDX analyses of different elements were recorded with the above instrument.

XRD studies

The lyophilized AgNPs coated on XRD grid were subjected to XRD analysis under SEIFERT JSO-DEBYEFLEX 2002 model operated at 40 kV and a current of 30 mA with Cu Kα radiation of wavelength 1.5406 Å. The XRD pattern was scanned in the 2θ range from 30° to 70° with a step size of 0.04°/s.

Fourier transform infrared spectroscopy

FTIR spectra of the aqueous leaf extract and AgNPs samples were analyzed by FTIR spectroscopy (Hitachi Ltd., Tokyo, Japan). The FTIR analysis was performed with KBr pellets and recorded in the range of 400–4,000 cm⁻¹. The various modes of vibrations were identified and assigned to determine the different functional groups present in the samples.

Antibacterial efficiency of biosynthesized AgNPs

The synthesized AgNPs obtained from the leaf extract of C. roxburghii was tested for its antibacterial potent against Gram-positive bacteria, such as Bacillus subtilis, Staphylococcus aureus, and Micrococcus luteus, and Gram-negative bacteria, such as Pseudomonas aeruginosa, Escherichia coli, and Enterobacter aerogenes. The antibacterial activities of the sample were determined by following the agar plate well diffusion method using 30 mL of Mueller Hinton agar medium in sterilized Petri plates. The agar plates were seeded with freshly prepared different pathogens. Agar wells with diameter of 6 mm were made with the help of a sterile stainless steel cork borer. The wells were labeled as A, B, C, and D. The wells A and B were loaded with 40 μL of the biosynthesized AgNPs and AgNO₃ (1 mM); C well was loaded with 40 μL containing 10 μg of the streptomycin. The D well was loaded with 40 μL of the aqueous leaf extract of C. roxburghii. The plates were incubated at 37°C for 24 hours, and the zone of inhibition (ZOI; mm) appearing around the wells was recorded.

Minimum inhibitory concentration

The microbial activity of AgNPs was recorded by the determination of minimum inhibitory concentration (MIC). The selected six different bacterial suspensions were prepared and seeded on the agar medium. Then 10 µL, 20 µL, 30 µL, and 40 µL of AgNPs were loaded to the respective wells. All the plates were incubated at 37°C for 24 hours, and the MIC concentration was recorded.

Antimicrobial activity of AgNPs loaded on cotton fabrics and SEM studies

The respective MIC concentration of AgNPs of the pathogens was added on the pre-sterilized white cotton cloth of 1 cm² under aseptic condition and tested against the six different pathogenic bacteria. The cloth was then placed in a sterile container and kept at 50°C for overnight to evaporate the water content. Then the pathogens, such as B. subtilis, S. aureus, M. luteus, P. aeruginosa, E. coli, and E. aerogenes, were seeded uniformly on the respective plates and placed on the cotton cloth impregnated with AgNPs. The plates were then incubated at 37°C for 24 hours, and the ZOI was recorded. Concurrently, the cotton cloth impregnated with AgNPs was also observed under scanning electron microscopy Hitachi S-3400N.

Results and discussion

UV–visible spectroscopy

C. roxburghii leaf (Figure 1) aqueous extract added with silver nitrate at 1 mM showed a change in color from pale yellow to dark brown (Figure 2). This was due to the excitation of surface plasmon resonance (SPR) by...
AgNPs are free electrons, which give rise to SPR absorption band, due to the combined vibration of electrons of metal nanoparticles in resonance with the light wave. The reduction of AgNPs in the aqueous solution of silver complex during the reaction with the leaf extract of *C. roxburghii* was confirmed by the UV–visible spectra. Absorption spectra of AgNPs at 430 nm after 24 hours of incubation sharpening of peak indicated that the particles are found monodispersed. The AgNO₃ solution and *C. roxburghii* leaf aqueous extract alone did not show any peak between 300 nm and 700 nm (Figure 3).

### Stability of silver nanoparticles

**Time**

AgNPs synthesis was also evaluated under UV–visible spectroscopy at different durations (0 hour–2 months) in order to study the stability of the formed nanoparticles. It was recorded that with increased contact time, the peak becomes sharper. The reaction had started within 6 hours, and the SPR showed a peak at 420 nm. Thereafter, there was a shift in the peak from 426 nm at 12 hours and 428 nm at 18 hours. The reaction ended at 24 hours with an absorption peak at 430 nm, and the two-month old sample also exhibited a peak at 430 nm (Table 1).

#### HR-TEM and EDAX analysis

Morphology and particle size of AgNPs were characterized using HR-TEM. The HR-TEM images of AgNPs synthesized with the leaf extract of *C. roxburghii* are shown in Figure 5A and B. The particles are predominantly spherical in shape with a diameter ranging from 10 nm to 30 nm. The EDAX (Figure 5C) spectrum shows a single signal for silver, indicating that the synthesized AgNPs were free from impurity. The strong signal of the Ag atoms indicated the crystalline

property. The presence of O peaks along with the Ag signals suggested that the AgNPs are capped by phytoconstituents through oxygen atom.

**XRD analysis**

The XRD patterns of AgNPs synthesized from the leaf aqueous extract of *C. roxburghii* were assigned to a face-centered cubic\(^2\) (Figure 6). The Bragg reflections with 2\(\theta\) values of 38.1\(^{\circ}\), 44.3\(^{\circ}\), and 64.4\(^{\circ}\) corresponded to the (111), (202), and (220) sets of lattice planes, and they may be indexed as the band for face-centered cubic structures of silver.\(^3\) The XRD pattern, thus, clearly illustrated that the AgNPs synthesized by the present green method are crystalline in nature.

Fourier transform infrared spectroscopy

The FTIR spectrum explains the interaction of AgNPs with leaf biomolecules of *C. roxburghii*. It showed the broad-band at 3,422 cm\(^{-1}\) due to the stretching vibrations of –N-H and –O-H groups, while an absorption band at 2,920 cm\(^{-1}\) due to –C-H group. An absorption band appeared at 1,616 cm\(^{-1}\) due to the stretching vibration of C=C, while an absorption band at 1,376 cm\(^{-1}\) is due to the presence of C-N-like amine or C-O-like phenol groups. The two absorptions recorded at 1,246 cm\(^{-1}\) and 1,096 cm\(^{-1}\) are due to the presence of C-N (aliphatic amine) stretching vibration. The two weak bands at 825 cm\(^{-1}\) and 618 cm\(^{-1}\) are due to the out-of-plane bending vibrations of –O-H and C-H groups, respectively. The FTIR results confirmed the presence of –NH, –OH, C=C, and CH groups, which indicated that the plant extract containing the hydroxyl and amine groups substituted flavonoids (Figure 7A). The FTIR spectrum of the extract-AgNPs (Figure 7B) also exhibited similar FTIR spectral values, but the stretching vibration band at 1,377 cm\(^{-1}\) corresponds to the C–N stretching vibrations peak was blend, which is amine group peak.\(^{27}\) The peaks recorded at 1,376 cm\(^{-1}\) of the aqueous extract of *C. roxburghii* expressed in AgNPs indicated that the amino groups are partially utilized for the encapsulation and stabilization of AgNPs. Further, it is observed that the flavonoids\(^{32}\) act as a reducing agent, which reduces Ag\(^+\) to Ag\(^0\) and the amino group as a stabilizing agent in the green synthesis of AgNPs. Thus, the FTIR study reveals the multifunctionality of the aqueous extract of *C. roxburghii* where reduction and stabilization occur simultaneously.

**Antimicrobial activity of AgNPs loaded on cotton fabrics and SEM studies**

The AgNPs impregnated on cotton fabrics were tested against three different Gram- positive bacteria and three Gram- negative bacteria, and ZOI was recorded. The cotton fabrics without AgNPs (Figure 9A) without AgNPs (Figure 9B) also exhibited the efficacy of fabrics with AgNPs against pathogens is given in Figure 10B.\(^{31}\) The cotton fabrics without AgNPs did not show any antibacterial activity (Figure 10A). AgNPs-immobilized cotton cloth could find wide application in various fields. In hospitals, it could be used by medical practitioners as self-sterilizing coat or apron material since the practitioners are constantly exposed to pathogenic organisms, which are potent causes of series side effects. The cotton cloth immobilized with AgNPs can also be used as an antiseptic bandage material for wound dressing.\(^{36}\) Lee et al reported the antibacterial effect of the AgNPs-immobilized cloth material against Gram-positive, Gram-negative, and antibiotic-resistant bacteria.\(^{36}\) Skin-irritation tests of the AgNPs-immobilized cloth material on guinea pigs revealed...
no side effects. Interaction of AgNPs with human fibroblasts affected their fission, but it was not toxic. Though AgNPs are reported to cause no big health problems when administered into the body, argyria is always a problem, irrespective of the nanosize of silver. In daily life, AgNPs-impregnated clothing may find a good applicability in underwear and socks. However, further studies are required to verify if the bacteria develop resistance toward the nanoparticles and associated cytotoxicity of nanoparticles toward human cells before proposing their therapeutic use.

Conclusion

AgNPs were green synthesized using the leaf biomolecules of *C. roxburghii*. We demonstrated the possibility of using biologically synthesized AgNPs and their incorporation in cotton materials. The cotton fabrics incorporated with the AgNPs exhibited antibacterial activity against both Gram-positive and Gram-negative bacteria. Considering the observation from UV–visible absorption, stability, XRD, HR-TEM of the *C. roxburghii* synthesized AgNPs, the impregnated AgNPs on cotton fabric could play a vital role in biomedical application since it is pollutant free and eco-friendly.
