Abstract: Long thought to be "junk DNA", in recent years it has become clear that a substantial fraction of intergenic genomic DNA is actually transcribed, forming long noncoding RNA (lncRNA). Like mRNA, lncRNA can also be spliced, capped, and polyadenylated, affecting a multitude of biological processes. While the molecular mechanisms underlying the function of lncRNAs have just begun to be elucidated, the conditional regulation of lncRNAs remains largely unexplored. In genome-wide studies our group and others recently found hypoxic transcriptional induction of a subset of lncRNAs, whereof nuclear-enriched abundant/autosomal transcript 1 (NEAT1) and metastasis-associated lung adenocarcinoma transcript 1 (MALAT1) appear to be the lncRNAs most ubiquitously and most strongly induced by hypoxia in cultured cells. Hypoxia-inducible factor (HIF)-2 rather than HIF-1 seems to be the preferred transcriptional activator of these lncRNAs. For the first time, we also found strong induction primarily of MALAT1 in organs of mice exposed to inspiratory hypoxia. Most abundant hypoxic levels of MALAT1 lncRNA were found in kidney and testis. In situ hybridization revealed that the hypoxic induction in the kidney was confined to proximal rather than distal tubular epithelial cells. Direct oxygen-dependent regulation of MALAT1 lncRNA was confirmed using isolated primary kidney epithelial cells. In summary, high expression levels and acute, profound hypoxic induction of MALAT1 suggest a hitherto unrecognized role of this lncRNA in renal proximal tubular function.

Keywords: hypoxia-inducible factor, kidney, oxygen, proximal tubule, testis

Introduction

One of the most amazing outcomes of the high-throughput sequencing era is the discovery that approximately 75% of the genome is transcribed and that there might be approximately as many noncoding (nc) RNAs as protein-coding messenger RNAs (mRNAs). While most of our knowledge focuses on small ncRNA functions, much less is known about long noncoding RNA (lncRNA; >200 nucleotides). Several recent reports have shown that lncRNAs are involved in a wide variety of physiological or pathological processes including X-chromosome inactivation, stem cell specification, neurodegenerative disorders, and cancer.^{1,2} Mechanistically, lncRNAs located at regulatory DNA *cis*-elements can recruit RNA-binding proteins to trigger gene expression by transcriptional and/or epigenetic gene regulation.³⁻⁵ While many of these studies documented a transcriptional dysregulation of lncRNAs in pathological states, the actual mechanisms of conditional regulation of lncRNA expression under physiological conditions have scarcely been investigated.

Conditional regulation of mRNA expression is a major principle in the adaptation of cells and organisms to environmental changes. Conditional regulation of lncRNAs in cancer cell lines suggests that this class of RNA also plays a (largely unknown)

role in the adaptation to microenvironmental changes such as tumor hypoxia. However, as it is unlikely that this mechanism evolved in cancer cells, we set out to analyze lncRNA induction also in normal tissues of animals exposed to inspiratory hypoxia.

Hypoxia represents a major microenvironmental condition that profoundly impacts upon the regulation of several hundred protein-coding genes involved in the adaptation to limited oxygen supply. Hypoxia-inducible factor (HIF) is a heterodimeric DNA-binding protein usually composed of a constitutively expressed β subunit and either a HIF-1 α or a HIF-2 α subunit whose stability and activity are regulated by oxygen-dependent protein hydroxylation.^{6,7} HIF-1 α and HIF-2 α show distinct expression kinetics with HIF-1 α protein levels decreasing under prolonged hypoxia, while HIF-2 α levels are increasing, suggesting a HIF α isoform-specific kinetics of target gene expression.^{8–10}

During a microarray study using a prostate cancer cell line, we previously found that among 608 genes that were induced by at least twofold in hypoxic conditions, more than 20 encoded lncRNAs.¹¹ These data were confirmed by a recent genome-wide study which focused on the hypoxia-inducible expression of ncRNA species in a breast cancer cell line.¹² This study systematically demonstrated for the first time that not only the transcription of mRNA but also the transcription of virtually all RNA classes, including lncRNA, miRNA, piwiRNA, snRNA, and tRNA is conditionally regulated by hypoxia in cultured cells.

Based on their abundant and widespread expression, we focused on two highly conserved, mostly nuclear lncRNAs that were robustly induced by hypoxia: NEAT1 (nuclear-enriched abundant/autosomal transcript 1; also termed MEN β) and MALAT1 (metastasis-associated lung adenocarcinoma transcript 1; also termed NEAT2). NEAT1 is a 4 kb polyadenylated, unspliced lncRNA known to associate with proteins that demark paraspeckles (nuclear domains involved in mRNA retention) and to play a central role in paraspeckle formation.¹³ MALAT1 is a >6.5 kb lncRNA that has been shown to regulate RNA-splicing factors in nuclear speckles that serve the assembly, modification, and storage of splice factors.¹⁴ However, at least in one report, MALAT1 has been shown to translocate to the cytoplasm during the G₂/M phase, which was associated with the cytoplasmic translocation of hnRNP C required for cell cycle progression.¹⁵

Materials and methods

Cell culture and RNA interference

Human Hep3B hepatoma, HeLa cervical carcinoma, and MCF-7 breast cancer cells were cultured in high-glucose

Dulbecco's Modified Eagle's Medium (Sigma-Aldrich, St Louis, MO, USA). The authors advise that their study did not require ethics approval from the Cantonal Ethics Commission Zurich, as only established, commercially available cancer cell lines were used. Primary mouse kidney epithelial cells were isolated and cultured as reported previously.¹⁶ Hypoxic experiments were performed for 24 hours at 0.2% oxygen and 5% CO₂ in a gas-controlled glove box (InvivoO₂ 400; Ruskinn Technology Ltd, Bridgend, UK) as described previously.¹⁷ Stable knockdown MCF-7 cell lines were established by transduction with lentiviral particles containing short-hairpin RNA expression constructs followed by selection with puromycin as described before.¹⁰

Animal experimentation

Animal housing, hypoxic exposure (inspiratory O₂ concentration of 8% for 0–108 hours), and organ excision for RNA isolation of male C57BL/6 mice have been described previously.¹⁸ For in situ hybridization experiments, male C57BL/6 mice were exposed to 8% oxygen for 24 hours in a hypoxia tent (Coy Laboratory Products, Grass Lake, MI, USA). Control animals were maintained at ambient oxygen concentration. Animal experiments were conducted at the Zurich Integrative Rodent Physiology (ZIRP) facility with the appropriate consent from the Veterinary Office of the Canton Zurich (license number 126/13) following consent by the Animal Experimentation Commission of the Canton Zurich which ensures that the guidelines of the Animal Welfare Act will be followed.

lncRNA quantification

Total cellular RNA was extracted as previously described.¹⁹ Total RNA (2 μ g) was reverse transcribed (RT) using AffinityScript reverse transcriptase (Agilent, Santa Clara, CA, USA) and the cDNA levels were estimated by quantitative polymerase chain reaction (qPCR) using a SybrGreen qPCR reagent kit (Sigma-Aldrich) in a MX3000P light cycler (Agilent). Transcript levels were calculated by comparison with a calibrated standard and expressed as ratios relative to ribosomal protein L28 or β -actin mRNA levels for MCF-7 and mouse tissues, respectively.

In situ hybridization

Excised organs were embedded in Tissue Tek O.C.T. (Miles Scientific, Naperville, IL, USA), frozen in 2-methylbutane in liquid nitrogen and stored at -80°C before 20 μm cryosections were prepared and mounted on SuperFrost Plus slides (ThermoScientific, Waltham, MA, USA). In situ hybridization was performed according to standard protocols

essentially as described previously.²⁰ Briefly, following rehydration in phosphate-buffered saline and acetylation, the slides were prehybridized at room temperature for several hours and then incubated with digoxigenin-labeled cRNA probes (200 ng in 200 μ L hybridization buffer) at 60°C overnight. Following sequential washing steps in 5 \times saline sodium citrate (SSC), 0.2 \times SSC (20 \times SSC is 3 M NaCl, 0.3 M Na-citrate, pH 7.0), and Tris-buffered saline (TBS), the slides were blocked with 10% fetal calf serum in TBS for 2 hours and incubated with alkaline phosphatase-labeled anti-digoxigenin antibodies (3.75 U/mL; Roche, Basel, Switzerland) in TBS at 4°C overnight. After washing in TBS, bound antibodies were detected by nitro-blue tetrazolium and 5-bromo-4-chloro-3-indolyl-phosphate staining, and mounted in Mowiol-DABCO medium. For the preparation of a hybridization probe, a 597 nt fragment of MALAT1 was amplified by reverse transcription PCR (RT-PCR) using RNA derived from mouse liver and the primers forward-5'-taagtctcgagggttggaagccctagttc-3' and reverse-5'-acttaagcttcactgtgtgggagaccttgt-3'. Following subcloning into pBluescriptKS+, digoxigenin-labeled cRNA sense and antisense probes were synthesized using T3 and T7 RNA polymerases (ThermoScientific).

Results

Hypoxia-inducible expression of NEAT1 and MALAT1 lncRNAs in cultured cells in vitro

During a microarray study using PC3 prostate carcinoma cells, we detected a previously unrecognized strong oxygen-dependent regulation of lncRNAs, including NEAT1 and MALAT1.¹¹ As shown in Figure 1, robust, albeit somewhat variable, oxygen-dependent regulation of NEAT1

and MALAT1 lncRNA levels was confirmed by RT-qPCR (quantitative RT-PCR) in a number of additional cancer cell lines, including Hep3B hepatocellular carcinoma, HeLa cervical carcinoma, and MCF-7 breast carcinoma, following 24 hours of exposure to 0.2% oxygen.

Preferential HIF-2 α isoform-specific regulation of NEAT1 and MALAT1 lncRNAs

Stable shHIF-1 α and/or shHIF-2 α MCF-7 knockdown breast cancer cell lines were used to assess the role of the HIF α isoforms in NEAT1 and MALAT1 regulation. As shown in Figure 2, both NEAT1 and MALAT1 showed an increased hypoxic induction following knockdown of HIF-1 α . Because we previously established that in these (and other) cell lines knockdown of either HIF α isoform leads to an increase in the other isoform,^{10,21} this result points to a preferential role of HIF-2 α in the induction of NEAT1 and MALAT1 gene expression. Indeed, compared with shHIF-1 α , shHIF-2 α as well as shHIF-1/2 α MCF-7 cells showed a significant attenuation of the hypoxic induction of both NEAT1 and MALAT1 lncRNAs. By contrast, the classical HIF-1 target gene carbonic anhydrase 9 (CAIX) displayed an exclusive dependency on HIF-1 α in the same experiment (Figure 2).

Hypoxic induction of NEAT1 and MALAT1 lncRNAs in mouse organs in vivo

To analyze the oxygen-dependent regulation of lncRNAs in vivo, groups of three mice were exposed to 8% O₂ inspiratory normobaric hypoxia for 0–108 hours. Eight percent of O₂ has been chosen as a compromise between maximizing the hypoxic response and minimizing the animal burden. Whole

Figure 1 Oxygen-dependent regulation of the lncRNAs NEAT1 and MALAT1 in vitro.

Notes: The indicated cell lines were exposed to 20% (normoxia) or 0.2% (hypoxia) O₂ for 24 hours. lncRNA levels were determined by RT-qPCR and displayed as ratio to the mRNA levels of the housekeeping ribosomal protein L28 which served as constitutive control. Shown are mean values + SEM of three independent experiments. The overall significance of the hypoxic induction of both lncRNAs was $P < 0.05$ as assessed by Student's *t*-test.

Abbreviations: lncRNAs, long noncoding RNAs; NEAT1, nuclear-enriched abundant/autosomal transcript 1; MALAT1, metastasis-associated lung adenocarcinoma transcript 1; SEM, standard error of mean; RT-qPCR, quantitative reverse transcription polymerase chain reaction.

Figure 2 HIF α isoform-dependent regulation of the lncRNAs NEAT1 and MALAT1.

Notes: Stable control shRNA (shCtrl), shHIF-1 α and/or shHIF-2 α knockdown was achieved by exogenous shRNA expression in MCF-7 cells. Following exposure to 20% (normoxia) or 0.2% (hypoxia) O₂ for 24 hours, lncRNA levels were determined by RT-qPCR, normalized to the mRNA levels of the housekeeping ribosomal protein L28, and displayed as fold hypoxic induction. Shown are mean values + SEM of 4–5 independent experiments (* $P < 0.05$, Student's t -test).

Abbreviations: lncRNAs, long noncoding RNAs; mRNA, messenger RNA; NEAT1, nuclear-enriched abundant/autosomal transcript 1; MALAT1, metastasis-associated lung adenocarcinoma transcript 1; shHIF, short-hairpin hypoxia-inducible factor; shRNA, short-hairpin RNA; RT-qPCR, quantitative reverse transcription polymerase chain reaction; SEM, standard error of mean.

organ levels of NEAT1 and MALAT1 lncRNAs were determined by RT-qPCR and normalized to β -actin mRNA levels which did not show any hypoxic alteration. As illustrated in Figure 3, in comparison with β -actin mRNA, NEAT1 (in heart and kidney) and especially MALAT1 lncRNA showed considerably high basal expression levels and a rather high degree of

interindividual variability. While NEAT1 lncRNA levels were only slightly induced by chronic (108 vs 0 hours) inspiratory hypoxia in heart, lung, and brain, MALAT1 was induced in most organs measured, with particularly high induction rates in spleen, kidney, testis, lung, and brain. Of note, mainly in kidney, testis, and lung, a marked induction of MALAT1

Figure 3 Oxygen-dependent regulation of the lncRNAs NEAT1 and MALAT1 in vivo.

Notes: Groups of three mice were exposed to an inspiratory O₂ concentration of 8% for 0, 4, 24, and 108 hours as indicated. Whole organ lncRNA levels were determined by RT-qPCR and displayed as ratio to the β -actin constitutive control mRNA levels in Log₂ scale.

Abbreviations: h, hours; lncRNAs, long noncoding RNAs; mRNA, messenger RNA; NEAT1, nuclear-enriched abundant/autosomal transcript 1; MALAT1, metastasis-associated lung adenocarcinoma transcript 1; RT-qPCR, quantitative reverse transcription polymerase chain reaction.

Figure 4 In situ expression of the lncRNA MALAT1 in vivo. Mice were exposed to normoxia or hypoxia (8% O₂) for 24 hours.

Notes: In situ hybridization was performed with digoxigenin-labeled antisense or sense probes followed by detection with alkaline phosphatase-labeled anti-digoxigenin antibodies and nitro-blue tetrazolium and 5-bromo-4-chloro-3-indolyl-phosphate staining using kidney (A) and testis (C) tissue slices. (B) MALAT1 positive renal proximal and distal tubules of three visual fields were counted and shown as mean values + SEM of three independent sections (* $P < 0.001$, Student's *t*-test).

Abbreviations: h, hours; lncRNAs, long noncoding RNAs; MALAT1, metastasis-associated lung adenocarcinoma transcript 1; SEM, standard error of mean.

lncRNA was already detected following acute inspiratory hypoxia of only 4 hours. Because such fast and strong hypoxic changes in expression levels are rather unusual in tissues in vivo, these results suggest a physiological role of MALAT1 in the systemic response to hypoxia.

Hypoxic induction of MALAT1 in proximal tubules of the kidney

Because the highest MALAT1 lncRNA levels, relative to β -actin mRNA levels, were found in kidney and testis, we focused on these two organs for further analysis by in situ hybridization. As shown in Figure 4A, MALAT1 was

mainly detected in renal tubular epithelial cells. Hypoxic exposure (8% O₂ for 24 hours) significantly increased both signal intensity and the number of positive cells. Quantification of the number of MALAT1 positive tubules revealed that proximal but not distal tubules account for the hypoxic induction of MALAT1 lncRNA expression (Figure 4B). In testis, the most outer layer of the seminiferous tubuli was positive for MALAT1 (Figure 4C), suggesting a putative functional role of MALAT1 in spermatogonia. Probably due to the constitutive hypoxic nature of the testis,²² no clear change upon hypoxic exposure could be detected by in situ hybridization (data not shown).

Figure 5 Oxygen-dependent regulation of the lncRNAs NEAT1 and MALAT1 in primary renal epithelial cells.

Notes: Epithelial cells were isolated from mouse kidney and exposed to 20% (normoxia) or 0.2% (hypoxia) O₂ for 24 hours. β-Actin mRNA and lncRNA levels were determined by RT-qPCR and corrected for the mRNA levels of the housekeeping ribosomal protein S12 which served as internal control. Shown are hypoxic induction factors as mean values + SEM of three independent experiments (**P* < 0.05, Student's one-tailed *t*-test).

Abbreviations: lncRNAs, long noncoding RNAs; mRNA, messenger RNA; NEAT1, nuclear-enriched abundant/autosomal transcript 1; MALAT1, metastasis-associated lung adenocarcinoma transcript 1; RT-qPCR, quantitative reverse transcription polymerase chain reaction; SEM, standard error of mean.

Oxygen-dependent regulation of NEAT1 and MALAT1 lncRNAs in primary mouse kidney epithelial cells

In principle, *in vivo* regulation of MALAT1 lncRNA by inspiratory hypoxia could result from indirect physiological effects, such as hormonal or sympathetic stimulation, rather than from direct tissue hypoxia. To address this issue, primary epithelial cells were isolated from mouse kidney and exposed to 20% or 0.2% O₂ for 24 hours. β-Actin mRNA, NEAT1 and MALAT1 lncRNAs were determined by RT-qPCR and normalized to ribosomal protein S12 mRNA levels. As shown in Figure 5, β-actin mRNA is not induced by hypoxia, confirming its suitability as a constitutive control gene for the *in vivo* experiments (Figure 3). In contrast to the constitutive expression and low variance of β-actin mRNA, NEAT1 and MALAT1 lncRNAs were induced by hypoxia, albeit with a high variance like found before in the kidney *in vivo* (Figure 3). Only hypoxic induction of MALAT1 lncRNA reached a statistically significant difference when compared with β-actin mRNA induction (Figure 5), indicating that oxygen is a direct regulator of renal MALAT1 lncRNA expression.

Discussion

During the course of genome-wide studies in PC3 prostate and MCF-7 breast cancer cells, our group and others noticed that there is no principal difference between lncRNA and mRNA expression with regard to the frequency and inducibility of transcriptional regulation by HIFs.^{11,12} NEAT1 and

MALAT1 were among the lncRNAs most strongly induced by hypoxia. In this study, we confirmed this initial observation in several additional cancer cell lines, suggesting that NEAT1 and MALAT1 could serve as general lncRNA biomarkers for tumor hypoxia, which is usually associated with adverse clinical outcome.

While the physiological relevance of oxygen-dependent MALAT1 regulation remains to be elucidated, hypoxia-inducibility of NEAT1 has recently been reported to induce paraspeckle formation, in line with its function as an architectural component of paraspeckles. While the precise function of paraspeckles is still unclear, Choudhry et al²³ demonstrated that NEAT1 was required for the hypoxic induction and nuclear retention of F11R/JAM1 mRNA. F11R mRNA encodes a regulator of tight junction assembly and was previously known to be subjected to increased RNA editing under hypoxic conditions.²⁴ Consistent with our findings, HIF-2 rather than HIF-1 induced NEAT1 in hypoxic breast cancer cell lines and solid tumor models.²³ Interestingly, in a recent report, it has been shown that MALAT1 is hypoxically induced in endothelial cells *in vitro* and is involved in balancing proliferative and migratory properties of these cells during vascular growth *in vivo*.²⁵

Several additional recent studies identified specific lncRNAs that are regulated by oxygen and often play crucial roles in cancer progression. Among others, the lncRNAs AK058003, H19, HINCUT-1, UCA1, linc-RoR, lincRNA-p21, HOTAIR, and EFNA3-derived lncRNAs have all been reported to be induced by hypoxia, usually in a HIF-1 dependent manner.^{26–33} Finally, the HIFα loci themselves have been reported to generate lncRNAs. The *HIF1A* antisense lncRNA HIF1A-AS1 has been implicated in apoptosis regulation.³⁴ HIF1A-AS2 lncRNA is overexpressed in clear cell renal cell carcinoma, can be hypoxically induced in lymphocytes, affects HIF signaling, and was later also found in several other cancer types as well as in normal tissues.^{35–38} The *EPAS1* (*HIF2A*) promoter upstream transcript HIF2PUT lncRNA has been reported to be a regulatory factor for osteosarcoma stem cells.³⁹

However, none of these reports addressed the question of whether these lncRNAs are induced by physiological hypoxia in normal tissues. Therefore, to the best of our knowledge, our study is the first to describe hypoxic induction of lncRNA in mouse tissues *in vivo*. Of note, kidney and testis were the two organs with highest hypoxic levels of MALAT1 lncRNA. Common to both organs are physiologically low tissue oxygen partial pressures.^{22,40} Typically, bioluminescence in normoxic

mice constitutively expressing a luciferase protein fused to the oxygen-dependent degradation domain of HIF-1 α can be readily observed in kidney and testis but not in other organs,⁴¹ consistent with the role of HIF in the oxygen-dependent regulation of MALAT1 lncRNA in vivo.

Conclusion

High expression levels and acute hypoxic induction of MALAT1 in several mouse organs suggest a hitherto unrecognized role of this lncRNA in systemic adaptation hypoxia.
