Objective: There is increasing evidence supporting the role of platelets in atherosclerotic vascular disease. The G-protein-coupled receptor P2Y₁₂ is a central mediator of platelet activation and aggregation but has also been linked to platelet-independent vascular disease. Ticagrelor is an oral P2Y₁₂ antagonist that is used as a standard treatment in patients after acute myocardial infarction. However, the effects of ticagrelor on advanced atherosclerosis have not been investigated.

Materials and methods: Twenty-week-old apolipoprotein-E-deficient mice received standard chow or standard chow supplemented with 0.15% ticagrelor (approximately 270 mg/kg/day) for 25 weeks. The lesion area was evaluated in the aortic sinus by Movat's pentachrome staining and lesion composition, thickness of the fibrous cap, and size of the necrotic core evaluated by morphometry. RAW 264.7 macrophages were serum starved and treated with ticagrelor in vitro for the detection and quantification of apoptosis. In addition, oxLDL uptake in RAW 264.7 macrophages was evaluated.

Results: A trend toward the reduction of total lesion size was detected. However, data did not reach the levels of significance (control, n=11, 565,881 μm^2 [interquartile range {IQR} 454,778–603,925 μm^2] versus ticagrelor, n=13, 462,595 μm^2 [IQR 379,740–546,037 μm^2 ; $P=0.1$). A significant reduction in the relative area of the necrotic core (control, n=11, 0.46 [IQR 0.4–0.51] versus ticagrelor, n=13, 0.34 [IQR 0.31–0.39]; $P=0.008$), and a significant increase in fibrous caps thickness (control, n=11, 3.7 μm [IQR 3.4–4.2 μm] versus ticagrelor, n=13, 4.7 [IQR 4.3–5.5 μm], $P=0.04$) were seen in ticagrelor-treated mice. In vitro studies demonstrated a reduction in apoptotic RAW 264.7 macrophages (control 0.07 $\pm$ 0.03 versus ticagrelor 0.03 $\pm$ 0.03; $P=0.0002$) when incubated with ticagrelor. Uptake of oxLDL in RAW 264.7 was significantly reduced when treated with ticagrelor (control 9.2 [IQR 5.3–12.9] versus ticagrelor 6.4 [IQR 2.5–9.5], $P=0.02$).

Conclusion: The present study demonstrates for the first time a plaque-stabilizing effect of ticagrelor in a model of advanced vascular disease, potentially induced by a reduction of oxLDL uptake or an inhibition of apoptosis as seen in vitro.

Introduction

Beyond hemostasis, platelets are critically involved in the initiation of atherosclerosis, but the effects of platelet activation throughout the atherosclerotic process within the already established lesions are unclear. In vitro studies demonstrate that platelets adhere to intact but activated endothelium as an initial step in atherogenesis.¹ Platelet-induced alterations of the endothelium support chemotaxis, adhesion, and transmigration of monocytes into

vessel walls, a key step in atherosclerosis.^{2–4} Animal studies further confirm the critical role of platelet adhesion in atherosclerotic lesion formation and reveal anti-atherosclerotic properties, for example, of acetylsalicylic acid.^{5,6} Recently, the junctional adhesion molecule A has been identified to increase platelet inflammation leading to an increase in atherosclerotic lesion development.⁷ The G-protein-coupled receptor, P2Y₁₂, on platelets is implicated in cardiovascular disease, and inhibition of the P2Y₁₂ receptor is a well-validated and effective therapeutic target for the prevention of myocardial infarction and ischemic stroke.^{8–12} Therefore, European Society of Cardiology (ESC) guidelines recommend ticagrelor, in addition to acetylsalicylic acid, to treat acute coronary syndrome.^{10,11} Evidence further supports an anti-inflammatory role for P2Y₁₂ receptor inhibition.^{13–15} However, whether potential anti-atherosclerotic effects are mediated due to an inhibition of platelet activation or anti-inflammatory effects elsewhere in the vascular wall is not clear.

It has recently been demonstrated that inhibition of P2Y₁₂ on vessel walls attenuates early atherosclerotic lesion progression, whereas platelet P2Y₁₂ inhibition had no effect.¹⁶ In line with these findings, Li et al¹⁷ documented a reduction in atherosclerotic lesion size in apoE^{−/−}/P2Y₁₂^{−/−} double knockout mice.¹⁷

Collectively, these data show that P2Y₁₂ inhibition may exert further beneficial effects in addition to inhibition of platelet aggregation.

The aim of this study is to evaluate the effectiveness of P2Y₁₂ inhibition by ticagrelor treatment in a clinically relevant model of atherosclerosis. Clinically, atherosclerosis is detected and treated in late stages. To mirror this phenotype, we set up an animal model that displays advanced atherosclerosis. This setup is supported by clinical data showing beneficial effects of long-term treatment with ticagrelor in patients with a prior myocardial infarction.¹²

Materials and methods

Animals and drug administration

Dose finding

Female apoE^{−/−} mice with a C57BL/6 background were housed in the animal care facility at the University of Heidelberg in a temperature-controlled room on a 12-hour light cycle. The mice were randomized, at 8 weeks of age, to receive standard chow supplemented with ticagrelor (AstraZeneca, Gothenburg, Sweden), 0.05% (90 mg/kg/day) (n=3) or 0.1% (180 mg/kg/day) (n=3). Blood samples were collected on several days at different times of the day. Plasma was prepared within 30 minutes of blood sampling by centrifugation at 1,500× g for 10 minutes at 4°C. The plasma was transferred into tubes and stored at −20°C within 1 hour

of sample collection. Plasma concentration of ticagrelor was determined by protein precipitation and liquid chromatography mass spectrometry as described previously.¹⁸

Main study

At 20 weeks of age, the female apoE^{−/−} mice exhibited advanced atherosclerotic lesions within the aortic sinus. Twenty-five, 20-week-old female mice were randomized to receive chow supplemented with ticagrelor (0.15%, 270 mg/kg/day, n=13) or standard chow (control, n=12) (chow prepared by Altromin, Lage, Germany). The dose of ticagrelor was based on the clinically relevant plasma exposure and was modulated on the basis of the data of our prior dose-finding study. All animal procedures were approved by the Federal Animal Care and Use Committee of the Regierungspraesidium Karlsruhe. All animal-handling procedures were performed according to the Guide for the Care and Use of Laboratory Animals of the Guidelines of the Animal Welfare and approved by the local government (Regierungspraesidium Karlsruhe).

Animal sacrifice and preparation of tissues

Mice were sacrificed after 25 weeks of treatment (at 45 weeks of age) by deep sedation (Ketamine (CP Pharma, Burgdorf, Germany)/Xylazine (Alvetra, Neumuenster, Germany), intraperitoneal) and exsanguination while blood was collected from the inferior vena cava. The animals were perfused via left ventricle with 10 mL phosphate-buffered saline solution followed by resection of the aorta. Then, the mice were perfused with 4% buffered formalin for paraffin sections of the aortic root. The heart was dissected from each animal, and the aortic sinuses were embedded in paraffin followed by serial sectioning (5 μm). Every third section was stained with a modified Movat's pentachrome stain.¹⁹

Determination of plasma lipid concentration

Total plasma cholesterol and low-density lipoprotein (LDL) levels were enzymatically determined; Siemens Healthcare Diagnostics GmbH, Eschborn, Germany) at the time of sacrifice.

Evaluation of lesion size and lesion composition

Cross-sectional area of Movat's pentachrome stained sections was determined by using computer-assisted morphometry (Image J; Media Cybernetics, Inc., Rockville, MD, USA). Therefore, all the parts of the lesions of a section were measured and the median was calculated for each animal. Results of lesion sizes are reported as median and interquartile range (IQR) of cross-sectional lesions per group (data expressed in μm²). We further evaluated each section for characteristic features of plaque morphology/composition: thickness of the fibrous cap

(data given in μm) and size of the necrotic core (ratio of mean size of necrotic core/mean lesion area) by morphometry.

Immunohistochemistry

Tissue sections of the aortic sinus adjacent to the sites of maximum lesion area were dewaxed and rehydrated. Endogenous peroxidase activity was inhibited by incubation with peroxoblock (Zytomed Systems GmbH, Berlin, Germany). Monocytes/macrophages were detected by using a monoclonal rat anti-mouse Mac-2-antibody (WAK-Chemie Medical GmbH, Steinbach, Germany). Anti-Mac-2 or isotype control was incubated for 1.5 hours at room temperature. The sections were then incubated with the biotinylated secondary antibodies for 30 minutes, rinsed three times with phosphate-buffered saline, and incubated for 10 minutes with streptavidin at room temperature. Acetate buffer, 3-amino-9-ethylcarbazole (AEC)-chromogen substrate (Zytomed Systems GmbH) was used for visualization. In order to detect apoptosis, "In Situ Cell Death Detection Kit TMR red" was used by the protocol of the manufacturer (Roche Diagnostics GmbH Mannheim, Germany). For quantification of staining we used computer-assisted morphometry. The results of Mac-2 staining is presented as ration extend stained area/total area of the lesion. Results of apoptosis are given as the ratio of Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL)-positive areas/total lesion area (Image J; Media Cybernetics, Inc.).

Cell culture

A murine macrophage cell line, RAW 264.7 cells (ATCC, Manassas, VA, USA), was grown in Dulbecco's Modified Eagle's Medium (DMEM) (Gibco BRL, Karlsruhe, Germany) supplemented with 10% heat-inactivated fetal calf serum, glutamine (100 U/mL), penicillin (100 U/mL), and streptomycin (100 mg/mL). For incubation, cells were plated in a six-well plate.

Detection and quantification of apoptosis in RAW 264.7 cells

In order to induce apoptosis, cells were washed three times with phosphate-buffered solution and were grown in a serum-free medium (DMEM) for 8 hours. At the beginning of the experiment, ticagrelor (dissolved in Dimethylsulfoxid) was added at a final concentration of 0.1 μM . Following 8 hours of serum starvation, the cells were stained and fixed according to the manufacturers' protocol (In Situ Cell Death Detection Kit; Roche Diagnostics). Positive staining was determined using computer-assisted morphometry. Data are presented as the ratio of TUNEL-positive cells per total amount of cells (Image J; Media Cybernetics, Inc.).

OxLDL uptake in RAW 264.7 cells

Cells were pre-treated with ticagrelor at a final concentration of 0.1 μM (dissolved in Dimethylsulfoxid) for 4 hours. OxLDL (Hycultec, Beutelsbach, Germany) at a dose of 80 $\mu\text{g/mL}$ was added for another 20 hours. Cells were washed with phosphate-buffered solution and fixed, followed by an oil-red-o staining. A representative picture out of the plate was taken, and positive staining was determined using computer-assisted morphometry. Results of the two groups are presented as the ratio of oil-red-o positive granula per cell (Image J; Media Cybernetics, Inc.).

Statistical analysis

Ticagrelor levels, lipid levels, and body weight are expressed as mean $\pm$ standard error of the mean. Differences between mean values are determined with the two-tailed unpaired Student's *t*-test. For analyses of the lesion size Mann-Whitney *U*-test is performed and data are given as median and IQR. For the analysis of plaque morphometry and areas of positive staining, the groups were compared using the Mann-Whitney *U*-test as the data could not be assumed to be normally distributed. *P*-values <0.05 were considered as statistically significant. As this was an exploratory analysis, no adjustments for multiple testing were performed. Statistical analyses were done using GraphPad Prism version 6.00 (GraphPad Software, Inc., La Jolla, CA, USA).

Results

Dose finding

Ticagrelor levels

A dose-dependent increase in ticagrelor plasma levels was observed. Ticagrelor plasma exposure in mice receiving 0.05% (90 mg/kg/day) and 0.1% (180 mg/kg/day) ticagrelor was $0.28 \pm 0.2 \mu\text{M}$ and $0.99 \pm 0.7 \mu\text{M}$ ($P=0.0005$; Figure S1), respectively.

Animals

There was no relevant mortality during the treatment period ($n=1$, control group). For lesion evaluation, 24 mice were included.

Effect on plasma lipid level and body weight

At the time of necropsy, there were no significant differences in total plasma cholesterol, LDL, or body weight between the groups (Table 1).

Effect on maximum lesion area within the aortic sinus

Ticagrelor treatment for 25 weeks (from 20 to 45 weeks of age) induced a numerical reduction in lesion size, which

Table 1 Baseline characteristics (body weight and total cholesterol levels)

Treatment	Body weight (gram)	Total cholesterol (mg/dL)	LDL cholesterol (mg/dL)
Ticagrelor (mean $\pm$ SEM)	26 $\pm$ 0.4	363 $\pm$ 28	343 $\pm$ 26
Control (mean $\pm$ SEM)	27 $\pm$ 0.2	346 $\pm$ 18	328 $\pm$ 18

Note: There is no significant difference between the groups.

Abbreviations: LDL, low-density lipoprotein; SEM, standard error of the mean.

was not statistically significant (control, $n=11$, 565,881 [IQR 454,778–603,925 μm^2] versus ticagrelor, $n=13$, 462,595 [IQR 379,740–546,037 μm^2], $P=0.1$; Figures 1A and 2A).

Features of lesion composition

Size of the necrotic core within the aortic sinus

Ticagrelor treatment resulted in a reduction of the average necrotic core area within the aortic sinus, presented as the ratio of mean necrotic core area/mean lesion area (control, $n=11$, 0.46 [IQR 0.4–0.51] versus ticagrelor, $n=13$, 0.34 [IQR 0.31–0.39], $P=0.008$; Figure 1B).

Thickness of fibrous caps

Ticagrelor treatment resulted in significantly thicker fibrous caps compared with controls (control, $n=11$, 3.7 [IQR

3.4–4.2 μm] versus ticagrelor, $n=13$, 4.7 [IQR 4.3–5.5 μm], $P=0.04$; Figure 1C).

Macrophage content within the aortic sinus

No difference was seen in the area of positive staining for macrophages within the atherosclerotic lesions, which was expressed as the ratio of positive staining/total lesion (control, $n=5$, 0.04 [IQR 0.007–0.05] versus ticagrelor, $n=13$, 0.02 [IQR 0.02–0.04]; $P=0.9$; Figure 2B).

Effect on apoptosis – in vivo

There was no difference in apoptotic cells within the atherosclerotic plaque assessed by TUNEL staining (control 0.03 [IQR 0.01–0.05] versus ticagrelor 0.03 [IQR 0.01–0.04], $P=0.6$).

Figure 1 Atherosclerotic lesion composition within the aortic sinus after 25 weeks of ticagrelor treatment, 0.15% (270 mg/kg/day), starting at 20 weeks of age.

Notes: (A) Ticagrelor treatment lead to a trend in the reduction of total size of atherosclerotic lesions. However, this difference did not reach the levels of significance. Data are expressed as median and range ($P=0.1$). (B) Mice treated with ticagrelor showed a reduction in mean size of the necrotic core (ratio of necrotic core/total lesion area) within the atherosclerotic lesion. Data are expressed as median and range (* $P=0.008$). (C) Thicker fibrous caps could be observed in apoE^{-/-} mice treated with ticagrelor compared with chow-fed controls. Data are expressed as median and range (* $P=0.04$).

Figure 2 Representative examples of the histology of an atherosclerotic lesion within the aortic sinus in apoE^{-/-} mice at 45 weeks of age (control group).

Notes: (A) Movat's pentachrome staining of an advanced lesion (arrow). (B) Immunocytochemical staining for macrophages (mac-2, arrow) within an atherosclerotic lesion (control group).

Effect on apoptosis – in vitro

Apoptosis in RAW 264.7 macrophages was induced via serum starvation for 8 hours leading to a 1.5-fold increase in the ratio of TUNEL-positive cells/total amount of cells (0.03 ± 0.05 versus 0.04 ± 0.07 , $P=0.03$; Figure S2). Presence of $0.1 \mu\text{M}$ ticagrelor during the 8-hour serum starvation resulted in the reduction of apoptotic cells compared with controls (0.07 ± 0.2 versus 0.03 ± 0.2 ; $P=0.0002$; Figures 3A and 4).

Ticagrelor inhibits oxLDL-uptake in RAW 264.7 macrophages

Cells, pre-treated with ticagrelor and stimulated with oxLDL showed a significant reduction in oxLDL-uptake compared with controls, which is given as the ratio of stained

granula/cell (control 9.2 [IQR $5.3\text{--}12.9$] versus ticagrelor 6.4 [IQR $2.5\text{--}9.5$]; $P=0.02$; Figures 3B and S3A and B).

Discussion

Increasing evidence supports the role of platelet activation which leads to vascular disease. Platelet interaction with the endothelium initiates atherogenesis, which leads to the recruitment of leukocyte and the release of pro-inflammatory mediators.^{1–3,20–22} These effects are mediated, in part, by the Adenosine diphosphate-activated G-protein-coupled receptor P2Y₁₂.⁴ Inhibition of the P2Y₁₂ receptor, by the antagonist ticagrelor, leads to several anti-inflammatory effects that are not necessarily mediated by the inhibition of platelet activation or aggregation. It sounds reasonable that there are also other mechanisms within the vascular wall since

Figure 3 Reduction of apoptosis and oxLDL uptake in RAW 264.7 cells.

Notes: (A) Incubation of RAW 264.7 cells with $0.1 \mu\text{M}$ ticagrelor leads to a significant reduction of TUNEL-positive cells. Apoptosis was induced via serum starvation for 8 hours. Data are expressed as mean $\pm$ standard deviation ($*P=0.0002$). (B) Incubation of RAW 264.7 cells with $0.1 \mu\text{M}$ ticagrelor beginning 4 hours prior to an oxLDL stimulation for 20 hours leads to a significant reduction of oil-red o positive granula within the cells. Data are expressed as median and range ($*P=0.02$).

P2Y₁₂ is also expressed on vascular smooth muscle cells and can be upregulated within the atherosclerotic plaque leading to an induction of different inflammatory and pro-atherogenic mechanisms.²³ Furthermore, a reduction of serum C-reactive protein or CD 40 ligand has been shown in atherothrombotic patients when treated with P2Y₁₂ antagonists.²⁴ Recently, West et al¹⁶ demonstrated a role for vessel wall that expressed P2Y₁₂ in the initiation of atherosclerosis. However, no inhibition was seen with platelet-derived P2Y₁₂ inhibition, leading to the conclusion that in early disease pro-atherogenic effects

are mediated only by vessel P2Y₁₂ receptors. Furthermore, Li et al (2012)¹⁷ showed an atherosclerotic lesion reduction in apoE^{-/-}/P2Y₁₂^{-/-} mice at 25 weeks of age after 12 weeks on a high-fat diet.¹⁷

Considering clinical conditions, nearly all the cardiovascular patients have established atherosclerosis. Therefore, it is important to focus on the effects of P2Y₁₂ inhibition in advanced vascular disease. The experimental design employed in this study models advanced stages of atherosclerosis, in line with clinical presentation. A trend toward the

reduction in total atherosclerotic lesion size was seen after 25 weeks of ticagrelor treatment. However, this result was not statistically significant, which might also be due to the use of standard mouse chow instead of a high-fat “western type” diet. Standard chow was specifically used to avoid artefacts by cholesterol-induced massive inflammatory triggering.¹⁷ In contrast, some investigators prefer high-fat diet-induced lesions for the evaluation of very advanced and complex plaques. We did not add a high-fat diet group in this study, which might be considered as a limitation in our experimental setup. Besides total vessel narrowing, the stability of an atherosclerotic lesion determines the clinical outcome. Therefore, we further focused on lesion composition after ticagrelor treatment. Previously, an increase in fibrous content was observed by Li et al¹⁷ in apoE^{-/-}/P2Y₁₂^{-/-} double knockout mice. In line with this, we were able to demonstrate thicker fibrous caps as well as a reduction in necrotic core size in ticagrelor-treated mice. To our knowledge, this is the first data to demonstrate plaque-stabilizing effects with ticagrelor or any P2Y₁₂ antagonist. Furthermore, it is important to emphasize that this observation is made in an animal model of very advanced atherosclerosis.

Since macrophages play a pivotal role in initiation and early development of atherosclerosis, we also evaluated the macrophage content within atherosclerotic lesions after ticagrelor treatment. In contrast to the study of Li et al¹⁷ where a reduction in monocyte/macrophage infiltration in the apoE^{-/-}/P2Y₁₂^{-/-} mice at 25 weeks of age was detected, we could not measure any difference between the groups. This is explained by our chosen model of very advanced atherosclerosis in mice at 45 weeks of age. The more advanced and necrotic the lesions of apoE^{-/-} mice get, the cellular survival decreases and cells are therefore undetectable within the plaque.²⁵ Using the aortic root for atherosclerotic lesion evaluation is a standard method, next to lesion evaluation “en-face” or within the innominate artery. As a limitation, we cannot exclude that site-specific effects can bias our data. To explore the potential pathophysiological mechanisms behind our observations, we performed in vitro experiments with the macrophage cell line RAW 264.7 for the detection and quantification of apoptosis. Macrophages are an important cell type in plaque physiology. Evidence suggests the involvement of P2Y₁₂ receptors in the regulation of cell death.^{26,27} Webster et al²⁸ observed less neuronal injury in an ischemia model due to inhibition of P2Y₁₂. Using serum starvation as an appropriate approach to induce apoptosis in vitro, we were able to demonstrate a ticagrelor-induced inhibition of apoptosis in RAW 264.7 cells. However, we could not detect any effect within the

lesions of the aortic roots, which might also be explained by the advanced, cell-depleted fibrous plaques of older mice. One cannot exclude that apoptosis might be affected in early or intermediate atherosclerotic lesions. In addition, we set up an experiment to model oxLDL uptake by macrophages. We were able to demonstrate a ticagrelor-dependent reduction in oxLDL uptake, evaluated by oil-red-o staining. Knowing that these are only in vitro data, oxLDL-dependent transformation to foam cells is an important step in early and intermediate fatty streak/plaque development. It triggers lesion size and composition and therefore also plaque stability.

Considering the data of West et al,¹⁶ where they could not show any effect of ticagrelor and clopidogrel on mice aged 12–14 weeks, there might also be age- or better disease-stage-dependent effects of P2Y₁₂ inhibition.

Clinical data from the Platelet Inhibition and Patient Outcomes Trial study clearly demonstrated a reduction in overall mortality with ticagrelor as compared with clopidogrel in patients with acute coronary syndromes.¹⁰ Furthermore, recent data from the Prevention of Cardiovascular Events in Patients With Prior Heart Attack Using Ticagrelor Compared to Placebo on a Background of Aspirin-Thrombolysis in Myocardial Infarction trial showed a reduction in the risk for cardiovascular events in patients with a history of heart attack when treated with ticagrelor. More than half of the enrolled study subjects had a multivessel disease, which means a stage of advanced coronary atherosclerosis.¹² While considering these data, it is necessary to focus on the effects of P2Y₁₂ inhibition in models of advanced stages of atherosclerosis. Following new clinical outcome data, our study demonstrates for the first time a potential plaque-stabilizing effect of ticagrelor in a model of advanced vascular disease, and this is possibly due to the inhibition of apoptosis or oxLDL-uptake.

Conclusion

P2Y₁₂ inhibition is a guideline-recommended treatment in patients with a prior myocardial infarction. Furthermore, clinical data demonstrated the beneficial effects by long-term administration of the P2Y₁₂ inhibitor ticagrelor. However, effects on already existing atherosclerotic lesions have not been evaluated yet.

Our study demonstrates for the first time a potential plaque-stabilizing effect of ticagrelor in a model of advanced vascular disease which is consistent with its clinical effect in patients. Besides the effects on platelet aggregation, further studies will be necessary to focus on platelet-independent P2Y₁₂ effects.

Supplementary materials

Figure S1 Ticagrelor plasma concentration.

Notes: Mouse plasma concentration of ticagrelor after feeding mice for 3 weeks regularly with chow supplemented with 0.05% and 0.1% ticagrelor (blood samples were collected on several days at different times of the day). Data are expressed as mean $\pm$ standard deviation ($P=0.0005$). * $P=0.003$.

Figure S2 Serum starvation to induce apoptosis.

Notes: Induction of apoptosis when RAW 264.7 cells are grown in the absence of fetal calf serum for 8 hours. Data are expressed as mean $\pm$ standard deviation, ($P=0.03$). * $P>0.05$.

Figure S3 OxLDL uptake in RAW 264.7 cells.

Notes: Reduction of oxLDL uptake in RAW 264.7 cells following treatment with ticagrelor (A) compared to control (B). $P=0.02$. Arrows: oil-red-o positive granula within the cells.

Drug Design, Development and Therapy

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are the features of the journal, which

Submit your manuscript here: <http://www.dovepress.com/drug-design-development-and-therapy-journal>

Dovepress

has also been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
