Background: Peters’ anomaly (PA) is a rare form of anterior segment dysgenesis characterized by corneal opacity with varied degree of anterior chamber affection with associated defects in the posterior layers of the cornea.

Case presentation: We report the case of a 3-month-old male infant with bilateral corneal opacity since birth who was transferred from the pediatric unit for further ophthalmic care. He was diagnosed with PA with subsequent systemic-associated malformations including craniofacial defects and skeletal defects. He was managed minimally with topical mydriatics and antiglaucomatous drugs.

Conclusion: PA is an inevitable cause of blindness in developing countries due to poor infrastructure and limited resources.

Keywords: congenital corneal opacity, polydactyly, camptodactyly, clinodactyly

Introduction

Peters’ anomaly (PA) is a rare form of anterior segment dysgenesis characterized by corneal opacity with or without irido corneal and/or corneolenticular adhesions, with associated defects in the posterior layers of the cornea.1 Embryologically, PA may result from a faulty separation of the lens from the surface ectoderm or aberrant reattachment of the lens/iris to the cornea during development of the anterior chamber between the 4th and 7th gestational weeks.2 Corneal opacity obstructs the visual axis, leading to sensory deprivation, amblyopia, and severe visual impairment.3 Two clinical types of PA have been described, Type 1 and Type 2. In Type 1, 80% of cases present bilaterally with central and paracentral corneal opacity. The cornea is typically avascular; iris strands extend from the collarette, and systemic abnormalities are not usually present. In Type 2, cases are commonly bilateral with denser corneal opacity; there is often juxtaposition of the lens, and iris strands may or may not be present.4 We report the clinical presentation and difficulties linked to the management of this rare pathology at our hospital.

Case report

We report the case of a 3-month-old male infant with bilateral corneal opacity since birth who was transferred from the pediatric unit for further ophthalmic care. Written informed consent was obtained from the patient’s parents to publish this report. Prenatal and natal history were unremarkable apart from the fact that the mother, aged 35 years at the time of childbirth, was HIV positive. There was no family history of similar ocular disorders or other congenital anomalies. Upon initial ophthalmic examination, a positive light pursuit was found. There was a homogeneous bilateral central
corneal opacity without neovascularization. Ophthalmologic examination under general anesthesia revealed a deep anterior chamber with iris strands that crossed the anterior chamber from the iris. The lens was transparent on the edges and did not adhere to the cornea. The retina was difficult to evaluate because of central corneal opacity. The intraocular pressure measured with a Schiotz tonometer was respectively 18 mmHg and 20 mmHg in the right and left eye. Other malformed features found in the physical pediatric examination included: broadening of the nose base and microcephaly (Figure 1), bilateral polydactyly with camptodactyly, clinodactyly of the supernumerary finger (Figure 2), an umbilical hernia with hypochromic macules of the abdomen (Figure 3) and bilateral supernumerary toe with hypertrophy of the halluc (Figure 4). There were no genital, vertebral, or cardiac anomalies on pediatric physical examination. Laboratory examination revealed that the child was also HIV positive. The diagnosis of Peters plus anomaly Type 1 was made. Management consisted of the administration of mydriatics, one drop two times per day, 3 days a week. One drop of dorzolamide in the evening was also prescribed. Immediate penetrating keratoplasty (PKP) in both the eyes was advised. After being informed that this intervention was not available in our country, the parents did not bring the child back for further consultation, and were lost to follow-up.

**Discussion**

First described in 1906 by Dr Alfred Peters, PA is a rare congenital dysgenesis of the anterior segment. This disease mostly appears sporadically. However, both recessive and irregular dominant inheritance has been described. Regarding causative maternal infections during pregnancy, environmental and genetic factors have been incriminated in the development of congenital eye anomalies. In our case, gestational maternal infection with HIV was the only associated comorbidity found. The leading clinical sign of PA is nonvascularized central or paracentral congenital corneal opacity. Systemic-associated malformations found in our patient included craniofacial defects and skeletal defects. Similar findings were previously reported in Kenya by Mwenda. Mutations in B3GLCT have been shown to explain 100% of cases of classic Peters plus anomaly.
inferior compared to the results of earlier PKP. The surgical approach proved that the visual outcome of delayed PKP in PA was not inferior compared to the standard of care. In a series of 22 patients, Chang et al waiting for PKP, which, according to Parmley et al, remains the standard of care. In a series of 22 patients, Chang et al proved that the visual outcome of delayed PKP in PA was not inferior compared to the results of earlier PKP. The surgical management of PA in our setting is challenging, owing to the lack of adequate infrastructure to enable PKP, the cost of the procedure, and the lack of knowledge among patients and their guardians. Untreated, PA evolves to blindness either by sensory deprivation or, rarely, by spontaneous corneal perforation. We cannot comment on the outcome of this child since the parents did not come back for further follow-up.

Conclusion
PA is an inevitable cause of blindness in developing countries due to poor infrastructure and limited resources. The relationship between eye anomalies and the mother’s positive serology for HIV was not established in this case.

Acknowledgment
The authors thank the father of the patient for allowing them to film and to use the photos for scientific purposes.
