Background: Anxiety and depression are common psychological comorbidities that impact the quality of life (QoL) of patients. In this systematic review, we 1) determined the impact of anxiety and depression on outcomes in patients with osteoarthritis (OA) and 2) summarized unique challenges these comorbidities present to current OA management.

Patients and methods: A systematic literature search was performed using the OVID Medline and EMBASE databases until April 2016. Full-text research articles published in English from the year 2000 onward with a sample size of >100 were included in this review. Eligible research articles were reviewed and the following data were extracted: study author(s), year of publication, study design, and key findings.

Results: A total of 38 studies were included in the present review. The present study found that both anxiety and/or depression were highly prevalent among patients with OA. Patients with OA diagnosed with these comorbidities experienced more pain, had frequent hospital visits, took more medication, and reported less optimal outcomes. Management strategies in the form of self-care, telephone support, audio/video education programs, and new pharmacotherapies were reported with favorable results.

Conclusion: Anxiety and depression adversely impact the QoL of patients with OA. Physicians/caregivers are highly recommended to consider these comorbidities in patients with OA. Ultimately, a holistic individualized management approach is necessary to improve patient outcomes.

Keywords: osteoarthritis, anxiety, depression, impact, management

Introduction
Osteoarthritis (OA) is the most common musculoskeletal disease worldwide.1 It is characterized by degeneration of the articular cartilage, osteophyte formation, and asymmetric joint space narrowing.2 These changes often lead to significant pain and disability and create a substantial individual, societal, and economic burden.3,4 Since the incidence and prevalence of OA increase with age, longer life expectancy will only increase these measures in the future.5 Current management largely emphasizes on alleviating symptoms and improving function, but for many these interventions do not provide adequate symptom relief. This variability in symptoms and outcomes among individuals with OA cannot be explained by the disease pathology alone.

Several factors are being investigated to explain differences in patient-reported symptoms and outcomes, of which anxiety and depression have begun to emerge as strong candidates.6,7 Anxiety is defined as the presence of “fear or nervousness about what might happen”.8 When this fear produces behavioral and physiological changes, the Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-V)
denotes this as anxiety disorder. Depression, on the other hand, is defined as the presence of sad, empty, or irritable mood. Both anxiety and depression are accompanied by somatic and cognitive changes that can significantly affect an individual’s capacity to function. Outside of OA, studies have consistently reported that anxiety and depression have significant impacts on cardiovascular diseases, chronic respiratory disorders, and gastrointestinal conditions. Patients suffering from chronic painful disabling conditions frequently report anxiety and depression as comorbidities. This may predispose patients to experience pain more often, as recent evidence suggests that anxiety and depression can alter pain threshold levels. Since chronic pain in itself can cause or aggravate anxiety and depression, a vicious cycle begins, which can significantly impact the course and management of these chronic diseases.

Several studies have evaluated the concordance between OA, anxiety, and depression. Although substantial work has been conducted to elucidate the role of anxiety and depression in patients with OA, this study seeks to provide a comprehensive understanding regarding the impact these comorbidities have on OA symptoms, patient outcomes, and challenges they present towards disease management.

**Patients and methods**

**Eligibility criteria**

Original studies of 1) human subjects that 2) assessed anxiety or depression during any time point of the 3) OA disease course 4) regarding its impact on patient-reported symptoms and outcomes along with 5) different interventions employed to manage these comorbidities were included for this review. We limited eligibility to studies that were only in English language. Review articles, letters to the editor, published abstracts, book series, short surveys, notes, editorials, and case series were excluded. It has been reported that even with statistically significant results, studies with low sample sizes are less likely to reflect a true effect; therefore, reports concerning <100 patients were excluded. Additionally, only articles with full-text versions published from the year 2000 onward were eligible for this review to focus on recent updates in OA, anxiety, and depression.

**Search strategy and criteria**

A manual electronic search of the OVID Medline (from 1996) and EMBASE (from 1974) databases was performed in duplicate by two authors (AS and PK) to identify studies published until April 2016 that assessed the impact or management of anxiety or depression in patients with OA. The following search string was used: “(osteoarthritis) and (anxiety or depression) and (impact or management)”.

One thousand and sixty-seven records were identified after excluding non-English results. After performing automated deduplication using the OVID search interface, 866 studies remained.

**Study selection**

Citation records were extracted to Excel spreadsheet software (Microsoft Corp, Redmond, WA, USA) and sorted by publication-type metadata. No specialized systematic review software packages were used. Publication types not meeting inclusion criteria were removed (Figure 1). These records were manually screened for eligibility by two authors (AS and PK), and any doubt regarding inclusion/exclusion of a particular study was addressed by discussion between the two authors. Unresolved conflicts were managed by discussion with two additional authors (QS and RG). Four hundred and thirty-five records were excluded as 233 were review

---

**Figure 1** Flow diagram summarizing the literature search, screening, and review.
articles, 174 were published abstracts, seven were conference papers, seven were notes, six were editorials, three were short surveys, two were letters, two were meta-analysis, and one was a book series. After excluding further 356 records based on title and abstract information, 21 records with a sample size of <100, and 16 records based on year of publication, 38 records were included in the final review. No systematic search of article bibliographies or conference proceedings was performed in an attempt to identify any additional unpublished or otherwise unidentified data. Full-length articles of the remaining 38 records were obtained and included in our final synthesis (Table 1).

Data collection

Data extraction included the following elements: 1) authors, year of publication, 2) study design, and 3) key findings.

Study designs and study quality

Of all the final studies included in this review, six were randomized controlled trials, 18,33,39,40,52,54 14 were prospective cohort studies, 20,21,30,31,34,37,41,44,46,49,49,51,55,56 14 were cross-sectional studies, 25,28,29,32,36,38,43,45,47,53,57 one was a retrospective analysis, 23 and three were surveys. 23,42,50

Results

Sample and setting

Of the original 866 English articles, 38 articles fulfilled our aforementioned criteria and thus were included for analysis in this review. 18-55 These 38 articles outline the impact of
anxiety and/or depression on patients living with OA and the challenges these comorbidities present in OA management, wherein some studies also examined approaches on how to address these challenges. The age of patients analyzed in most of these studies was consistent with the age at which OA and depression are commonly diagnosed. However, one study specified a younger cutoff age range in their inclusion criteria. Gignac et al\(^4\^5\) reported that middle-aged patients with OA (mean age 50.8 years) reported more depression compared to elderly subjects (mean age 67.8 years) having similar OA severity. This difference was attributed to role limitation and dissatisfaction among middle-aged OA individuals. Most studies included both male and female participants. However, in one study, sex was an eligibility criterion, as this study focused solely on female participants.\(^19\) Studies were carried out in different settings viz university hospital, general practitioner (GP) clinics, and via telephone/mailed surveys. All studies published after year 2000 were analyzed (Table 1).

### Anxiety and depression

All studies evaluated anxiety and/or depression either as a primary or a secondary objective. Various scoring methods were utilized, of which Centre for Epidemiological Studies Depression Scale (CES-D)\(^58\) and Hospital Anxiety and Depression Scale (HADS) were most popular.\(^59\) Both CES-D and HADS have been extensively used and studied, and are considered reliable and valid research tools.\(^60\) Other scoring methods used were Composite International Diagnostic Interview,\(^13\) 36-Item or the 12-Item Short Form Health Survey (SF-12, SF-36),\(^61\) Hopkins Symptom Checklist Depression Scale,\(^62\) Patient Reported Outcome Measurement Information System,\(^63\) Patient Health Questionnaire (PHQ),\(^64\) visual analog scale, Arthritis Impact Measurement Scale,\(^65\) Beck Depression Inventory,\(^66\) and the Health Education Impact Questionnaire.\(^67\) Apart from these scores, clinical diagnosis based on patient interviews was also utilized.

### OA pathology and disease severity

Most studies focused on lower extremity OA (hip and knee), with one study examining hand OA\(^38\) patients. Diagnosis was based on clinical presentation or radiographs. Patients from the entire spectrum of disease severity were studied. The Kellgren and Lawrence (KL) radiographic grading system was most often used to report OA severity; however, some studies did not use any specific grading method. One study included patients with early (KL I, II) and late (KL III, IV) stage OA.\(^32\) Pain was a consistent feature across most studies and was assessed primarily using the Western Ontario & McMaster Universities Osteoarthritis Index.\(^68\) In addition to OA, two studies also assessed patients with rheumatoid arthritis.\(^19,33\)

### Epidemiology of anxiety and depression in patients with OA

Three studies reported on the prevalence of anxiety and depression in patients with OA.\(^24,29,41\) Rosemann et al\(^29\) conducted a cross-sectional survey in 1,021 patients with OA and reported that psychological factors (viz anxiety and depression) were highly prevalent among the patients (19.76% of male and 19.16% of female participants reported a PHQ-9 score of \(\geq 15\)). Similar results were reported by Sale et al\(^24\) in a cross-sectional study where 21.3% of 1,227 participants reported a CES-D score of \(\geq 16\). Likewise, Kirkness et al\(^41\) reported that major depressive disorder was commonly prevalent in patients scheduled for total knee arthroplasty.

### Impact

#### Impact of anxiety and depression on OA symptoms

Of the 38 studies included in our final analysis, 13 studies examined the impact of anxiety and depression on OA symptoms.\(^18,19,26,31,32,38,45,46,48,50,55\) There was a considerable overlap in reporting impact of these psychological conditions on patients with OA with pain being the key central element. Studies reported that the prevalence of anxiety and depression was interrelated to index joint pain,\(^35\) pain at multiple sites,\(^31,50\) pain intensity,\(^25\) and OA severity.\(^32\) Pain was in turn associated with depression and its recurrence.\(^46\) Hawker et al\(^43\) also reported that current OA pain predicted future fatigue, disability, and depressed mood. In addition to its impact on OA pain, concurrent depression was also interrelated to significant participation restriction and physical limitation.\(^26,45\)

#### Impact of anxiety and depression on OA outcomes

Nine studies examined the impact of anxiety and depression on the outcomes of patients with OA.\(^20,27,38,34,35,37,44,52,55\) Studies reported that anxiety and depression increased GP visits,\(^32\) health care utilization,\(^27\) drug prescriptions,\(^53\) adversely affected surgical outcomes,\(^30,34,35,37,44\) and increased postsurgical pain.\(^20\)

### Impact of anxiety and depression on patients with OA: sex differences

Our results indicate that anxiety and depression differentially impact lives of male and female patients with OA.
Sale et al\textsuperscript{24} reported that higher level of depressed mood was independently and significantly associated with the female sex.

**Management challenges**

Thirteen studies evaluated management challenges in patients with OA with comorbid anxiety and depression.\textsuperscript{21,22,23,33,36,39,40,42,47,49,51,54} The present study found that anxiety and depression posed unique challenges to physicians in 1) diagnosis, 2) structuring a proper management plan, and 3) effective pharmacotherapy.

**Challenges in diagnosis of anxiety and depression**

Primary care physicians or GPs infrequently considered or found it difficult to diagnose anxiety and/or depression in patients with OA.\textsuperscript{28,42}

**Challenges in self-care, collaborative care, social/phone support**

Management regimes advocating self-care, social/phone support, and educational engagements in patients with OA with comorbid anxiety and depression were reported. Lin et al\textsuperscript{39} reported that systematic depression management (antidepressant pharmacotherapy and/or problem-solving treatment) was more effective than usual care in decreasing pain severity among patients with arthritis with lower initial pain severity, but not among patients with higher initial pain severity. On the contrary, Buszewicz et al\textsuperscript{52} reported that although self-management reduced anxiety, it had no significant effect on pain, physical functioning, or number of GP visits at 12 months.

**Challenges in pharmacotherapy**

Pharmacological challenges exist in managing patients with OA with comorbid anxiety and depression. These challenges juxtaposed with the demographics of this patient cohort (advanced age and presence of other medical comorbidities) make pharmacotherapy difficult. Therefore, it is vital to investigate new treatment modalities that could effectively manage these conditions with minimum adverse effects. The present study found that rofecoxib and tapentadol were reported to improve pain and depressive symptoms of patients with OA. Theiler et al\textsuperscript{21} assessed the effects of rofecoxib on quality of life (QoL) in elderly patients with painful OA flares who were not responsive to or had adverse reactions to previous NSAID therapy. The authors reported that rofecoxib significantly improved QoL, as measured by the SF-12. Similarly, Collantes-Esteve and Fernandez-Perez\textsuperscript{51} found rofecoxib to favorably influence patients with OA with self-reported depression. In addition to rofecoxib, use of tapentadol (prolonged and immediate release) has also been reported in patients with chronic painful knee OA. Steigerwald et al\textsuperscript{52} evaluated effectiveness of tapentadol prolonged release in 195 patients with chronic OA knee pain and found significant improvement in pain intensity, QoL, SF-36, and HADS.

**New management approaches: music, video, and yoga**

In recent years, various new and innovative management methodologies have been investigated. Ayral et al\textsuperscript{54} reported that advocating video education information on the planned procedure before surgery lowered perioperative anxiety. Music therapy and yoga have also been reported to help improve patient anxiety and depression; however, the sample sizes of their respective studies were small.\textsuperscript{69,70}

**Discussion**

Psychological comorbidities (anxiety and depression) are highly prevalent among patients with OA.\textsuperscript{54,29,41,49} These comorbidities are frequently associated with higher pain and physical limitation, poor outcomes to both conservative and surgical interventions, and increased pharmacotherapy and health care utilization.\textsuperscript{23,48} Our results indicate that standardized interventions to manage these comorbidities are lacking as a number of different self-care management programs, telephone support programs, video information support programs, and new drug treatments were reported in the literature with varied success.\textsuperscript{21,22,23,33,36,39,40,42,47,49,51,54} This variability in patient care highlights the complex relationship that exists between OA, anxiety, and depression (Table 2). Yet, these comorbidities are commonly overlooked by many primary care physicians and GPs who either solely focus on physical aspects of OA or simply fail to assess patients’ psychological state altogether.\textsuperscript{71}

It is imperative to recognize these comorbidities, as these can influence disease course and management, ultimately affecting functional outcomes.

Anxiety and depression are interrelated with pain and physical limitation, the two key OA symptoms. Studies in our review have revealed that anxiety and depression can significantly impair QoL of patients by altering pain perception and functional capacity.\textsuperscript{24} Therefore, educating physicians about timely identification of psychosocial factors such as anxiety and depression that may pre-date OA pathology or result as a

Abbreviations: FDA, US Food and Drug Administration; GP, general practitioner; NICE, National Institute for Health and Care Excellence; OA, osteoarthritis.
OA can serve as an indicative factor for intensity of depression in patients with OA. This concept should be further investigated. Similarly, sex differences are prevalent independently in OA, anxiety, and depression. Studies have reported that female patients with OA report greater anxiety and depression and lower QoL than males. Moreover, female patients with OA may have different expectations than their male counterparts and therefore may require a completely different management approach.

It is important to state that present literature fails to fully address the management strategies in dealing with psychological comorbidities seen in patients with OA. It is rather clear that one treatment does not fit all, as seen in the present review. On one end self-management interventions did not improve pain, QoL, or depression, while on the other hand, self-management did produce improvement in exercise and relaxation activities in depressed patients although not as much as in patients without depression. These conflicting results highlight the challenges present in the management of these comorbidities today. It should also be highlighted that recruiting and retaining patients in management programs is also challenging and should be further evaluated to increase patient compliance, as depressed patients tend to lack interest from the outset. Furthermore, another factor in need of consideration is age, and how reports of depression/anxiety can differ based on patients’ age group. To garner an accurate understanding of how depression/anxiety interacts with OA, it is important to consider the possibility that different age groups experience varying degrees of depression/anxiety, based on a diverse set of factors, such as socioeconomic status and health complications. Recent trends in depression suggest its high prevalence among individuals aged 40–59 years, which may thus affect the presentation of OA to a greater degree in middle-aged cohorts than younger or elderly cohorts. Therefore, examining the impact and management challenges of anxiety and depression in an age-stratified OA cohort should be further investigated.

Although our results provide a comprehensive summary of the current state of literature, a considerable lack of studies originating from outside of North America and Europe is noted. This could be attributed to the fact that outpatient visits and in-patient admissions for mental health diseases are higher in the US and Europe, or it could simply underscore a general lack of research initiatives in the developing world, or that psychological conditions largely remain under-recognized and/or under-diagnosed. Thus, the inclusion of studies from developing nations may provide a more detailed picture of the relationship between anxiety, depression, and OA. We also acknowledge that the exclusion of reports not published in English may have introduced institutional bias. Furthermore, in addition to the inherent weaknesses of the studies reviewed, our study may be skewed by publication bias, as there is a well-described prejudice toward the publication of positive findings. Nevertheless, we believe that the present review accurately presents the current state of evidence concerning the impact and management challenges of anxiety and depression encountered by patients with OA.

**Conclusion**

In summary, the majority of evidence regarding impact of anxiety and depression in patients with OA suggests reduced QoL and poor clinical outcomes. The current literature fails to lay a blueprint to tackle the management challenges seen. OA stage-specific stratification may help guide management. However, further studies are needed to formulate definitive management strategies to deal with OA-associated anxiety and depression and should focus on high-quality randomized controlled trials with patients stratified into non-operative, pre-operative/operative, and post-operative groups.

**Acknowledgment**

We thank Dr Jason Rockel, Research Associate at Krembil Research Institute, for comments that greatly improved the manuscript.

**Disclosure**

The authors report no conflicts of interest in this work.
