New compounds in the management of venous thromboembolism after orthopedic surgery: focus on rivaroxaban

Lars Carl Borris
Department of Orthopaedic Surgery, Århus University Hospital, Århus, Denmark

Abstract: Rivaroxaban (Xarelto®) is a member of a new class of oral, direct (antithrombin-independent) factor Xa inhibitors, which restrict thrombin generation both in vitro and in vivo. After oral administration the absorption is near 100%, the bioavailability is near 80%, and the elimination half-life is 5–9 hours with mixed excretion via the renal and fecal/biliary routes. The pharmacokinetics of rivaroxaban are predictable and consistent with a rapid onset of antithrombotic action within 2 hours after administration. Phase II clinical studies have been carried out in patients undergoing total hip arthroplasty (THA) or total knee arthroplasty (TKA) and a dose of 10 mg once daily for thromboprophylaxis was selected for further clinical development. The results of the phase III studies showed a significantly better antithrombotic efficacy of rivaroxaban compared with enoxaparin both in the short term (10–14 days) in TKA patients and long term (35 ± 4 days) in THA patients with a comparable safety. Symptomatic thromboembolic events were also significantly reduced with rivaroxaban. Liver enzyme elevation was seen in patients treated with rivaroxaban, but there was no indication of an increased risk of liver toxicity compared with enoxaparin. In conclusion, rivaroxaban is a potent and safe new compound for antithrombotic prophylaxis in orthopedic surgery.

Keywords: deep vein thrombosis, oral direct factor Xa inhibitor, pulmonary embolism, rivaroxaban, thromboprophylaxis, total hip arthroplasty, total knee arthroplasty

Introduction

Total hip arthroplasty (THA) and total knee arthroplasty (TKA) are operations with a high risk of venous thromboembolic (VTE) complications and in the latest ACCP guidelines it is recommended to use prophylaxis with a low-molecular-weight heparin (LMWH), fondaparinux (a synthetic pentasaccharide) or adjusted-dose vitamin K antagonist (VKA) for at least 10 days after operation and to give extended prophylaxis for 28–35 days after THA and hip fracture surgery (Geerts et al 2004). Administration of LMWH and fondaparinux is subcutaneous and therefore these drugs are less suited for self-administration after discharge. Extended prophylaxis with enoxaparin after THA was cost-effective only when more than half of all patients were able to self-inject their treatment (Bergqvist and Johnsson 1999). Although administered orally, VKA is inconvenient to use due to the narrow therapeutic window and the need for repeated dose adjustments requiring laboratory monitoring. Thus, it has long been hoped that more convenient oral antithrombotic drugs would be discovered. The first step in this direction was when ximelagatran, an oral direct thrombin inhibitor, was introduced on the market. However, when safety reports from patients on extended prophylaxis after major orthopedic surgery indicated a risk of liver toxicity it was eventually withdrawn (Kenne et al 2008). Since then several other oral anticoagulant compounds have been developed and they are currently undergoing clinical evaluation in orthopedic surgery.
Borris

(Eriksson et al. 2005, 2007a; Lassen et al. 2007a). One of these is rivaroxaban (Xarelto®; Bayer HealthCare), a direct factor Xa (FXa) inhibitor (Perzborn et al. 2005).

**Review of pharmacology, mode of action, pharmacokinetics of factor Xa inhibitors**

Activation of factor X to FXa initiates the conversion of prothrombin to thrombin which leads to conversion of fibrinogen to fibrin and eventually clot formation (Figure 1). An invasive operative procedure cannot be performed without tissue damage resulting in release of tissue factor (TF). Orthopedic surgery due to surgical damage to bone is especially prone to TF release because bone marrow is rich in TF (Dahl et al. 1995). In conjunction with factor VIIa, TF activates FXa directly (the extrinsic pathway) or via propagation of the tenase complex (factor VIIa + factor IXa) on an activated platelet membrane (the intrinsic pathway) (Mann et al. 2003). The prothrombinase complex is then formed on the platelet surface and incorporation of FXa into this complex increases the rate of thrombin generation tremendously. The thrombin-generating efficacy of the prothrombinase complex is much more pronounced than that of free FXa (Mann et al. 1998; Rauch and Nemerson 2000; Mann et al. 2003a). Thus, FXa is the pivotal point in the coagulation cascade because it can be activated both by the extrinsic and the intrinsic pathways; furthermore the only function of FXa in the coagulation process is to promote coagulation and to amplify the events. Thus, it has been estimated that one molecule of FXa catalyzes the formation of ~1000 thrombin molecules (Mann et al. 2003b). In the design of new antithrombotic drugs it therefore seems attractive to target the mode of action towards inhibition of FXa. Unfractionated heparin (UFH) and LMWH are indirect FXa inhibitors because they inhibit FXa by potentiation of the natural inhibitory action of antithrombin (AT) that is an endogeneous plasma protein. In addition especially UFH also has an inhibitory action on several other coagulation factors among which factor IIa is the most important. Fondaparinux is a synthetic pentasaccharide with the same mode of action as UFH and LMWH, but in contrast to those it acts solely by the antithrombin-mediated inhibition of FXa (Samama and Gerotziafas 2003). On the contrary, direct FXa inhibitors, including rivaroxaban, do not need AT to exert their inhibitory action on FXa, because they are able to bind directly to the active site of FXa, thereby preventing interaction with its substrates. As a consequence the direct FXa inhibitors are able to inhibit both free FXa and FXa bound in the prothrombinase complex (Perzborn 2005) (Figure 1).

Rivaroxaban belongs to a new group of oral direct FXa inhibitors. The chemical structure is shown in Figure 2 and

![Diagram of the coagulation cascade with indication of mechanism of action of direct FXa inhibitors. Reproduced with permission from Bayer HealthCare.](image-url)

**Figure 1** Schematic representation of the coagulation cascade with indication of mechanism of action of direct FXa inhibitors. Reproduced with permission from Bayer HealthCare.
Multiple dose escalation study, rivaroxaban doses of 5 mg once, twice, and thrice daily, and 10 mg, 20 mg, and 30 mg twice daily were administered orally on days 0 and 3–7. The study showed no clinically relevant influence on bleeding time after treatment for 7 days and there were no signs of accumulation at any dose. A dose-dependent prolongation of PT, activated partial thromboplastin time (aPTT), and HepTest to a similar extent to inhibition of FXa were seen, and it was suggested that the inhibition of the FXa activity of rivaroxaban can be monitored by these clotting tests or by measurement of FXa alone (Kubitza 2005a). None of the studies showed problems with tolerability or safety with any dose or dosing frequency of rivaroxaban.

A number of interaction studies in healthy subjects between rivaroxaban and commonly used drugs such as acetylsalicylic acid (ASA) and nonsteroid acetylsalicylic acids (NSAID) were performed. Concomitant use of ASA in 500 mg and 100 mg doses and rivaroxaban at doses between 5 mg and 80 mg did not show any clinically relevant interaction (Kubitza et al 2006b). Rivaroxaban together with NSAID (naproxen) significantly increased bleeding time compared with rivaroxaban alone, but it was not clinically relevant (Kubitza et al 2007a). A comparative placebo-controlled study in 50 subjects treated with rivaroxaban or moxifloxacin (positive control) showed no prolongation of the QT-interval of rivaroxaban, and thus there is no need to monitor the QT-interval routinely in patients treated with rivaroxaban (Kubitza et al 2008).

With a half-life of 5–9 hours it would be expected that rivaroxaban should be administered at least twice daily to be effective. However, a crossover placebo-controlled study in which 12 healthy subjects received single oral doses of 5–30 mg of rivaroxaban showed that the endogenous thrombin potential was dose-dependently reduced by more than 80%, compared with baseline, and that the prothrombinase-induced clotting time in platelet-rich plasma was prolonged more than 1.8 times, both effects having a duration of 24 hours (Graff et al 2007). Thus, this would support a concept of once-daily administration. The clinical impact of these findings was further explored in the phase II program.

**Phase II program (dose finding)**

A series of dose-ranging studies was performed in patients undergoing THA or TKA and an overview of the results of these studies is given in Table 2. The first proof-of-principle study, which included patients undergoing THA, was an open-label, randomized study to assess the efficacy and safety of different doses of rivaroxaban relative to a standard regimen of

enoxaparin (Eriksson et al 2007b). Rivaroxaban was given as tablets in doses of 2.5 mg, 5 mg, 10 mg, 20 mg, and 30 mg twice daily and 30 mg once daily, started 6–8 h after surgery; enoxaparin was given by subcutaneous injection of 40 mg once daily started on the evening before surgery. The investigators were blinded to the dose of rivaroxaban, but not to the type of prophylaxis (rivaroxaban vs enoxaparin). The treatment continued for 5–9 days at which time a bilateral venography was performed to diagnose asymptomatic deep vein thrombosis (DVT); in cases of symptoms of DVT or pulmonary embolism (PE) during the study objective confirmation of the event was requested. The efficacy results with rivaroxaban were comparable with that obtained with enoxaparin, but with a flat dose response. The incidences of major bleeding were dose-dependent and at an acceptable level. In patients treated with rivaroxaban 30 mg once daily the efficacy result was comparable with the result in the enoxaparin group (15.1% vs 16.8%) and the incidence of major bleeding (4.5%) was within the expected range, which was the first indication that once-daily administration of rivaroxaban could be feasible (Table 2). The next two studies to follow were randomized, double-blind studies in THA or TKA patients, respectively (Turpie et al 2005; Eriksson et al 2006a). The dose regimens of rivaroxaban were 2.5 mg, 5 mg, 10 mg, 20 mg, and 30 mg administered orally twice daily started 6–8 h after surgery and the comparator was again subcutaneous injections of enoxaparin, 40 mg once daily started on the evening before surgery in the THA study, and 30 mg twice daily started 12–24 h after surgery in the TKA study. The duration of the treatment and timing of venography was the same as for the previously described study. The efficacy results obtained in both studies again showed a flat dose-response for rivaroxaban with incidences in the different dose groups that were comparable with the enoxaparin group in the individual study. The incidences of VTE in both treatment arms of the TKA study were much higher (25.4%–40.4% in the rivaroxaban groups and 44.3% in the enoxaparin group) than those seen in the THA study (7%–18% in the rivaroxaban groups and 17% in the enoxaparin group) (Table 2), which is not surprising after knee surgery based on previous reports (Gillespie et al 2000; Geerts et al 2004). The safety results with rivaroxaban were also at a comparable level with enoxaparin and clearly dose-dependent (Table 2). A pooled analysis of the two studies showed that total daily doses of rivaroxaban of 5–20 mg had the most favorable balance between antithrombotic efficacy and safety compared with enoxaparin (Fisher et al 2007). The last study in the phase II program was performed in patients undergoing THA, and in contrast to the previous studies it was decided that rivaroxaban was to be administered once daily in all dose groups (Eriksson et al 2006b). The following once-daily doses of rivaroxaban were studied: 5 mg, 10 mg, 20 mg, 30 mg, and 40 mg started 6–8 h after surgery, and for the comparator arm enoxaparin 40 mg injected subcutaneously once daily started on the evening before surgery was chosen. Treatment duration and timing of venography was the same as for the previously described studies. The primary efficacy end-point was observed in 6.4%–14.9% of patients in the different rivaroxaban dose groups, without any dose relation, and in 25.2% of the enoxaparin group; however, the study was not powered to show any

| THA (Eriksson et al 2007b) | Open, randomized | 2.5, 5, 10, 20, 30 bid | 359 | 10.2–23.8 | 16.8 | 2.5–10.8 |
| THA (Eriksson et al 2006a) | Double-blind, randomized | 2.5, 5, 10, 20, 30 bid | 442 | 7–18 | 17 | 0.8–5.4 |
| TKA (Turpie et al 2005) | Double-blind, randomized | 2.5, 5, 10, 20, 30 bid | 296 | 25.4–40.4 | 44.3 | 1–7.5 |
| THA (Eriksson et al 2006b) | Double-blind, randomized | 5, 10, 20, 30, 40 od | 511 | 6.4–14.9 | 25.2 | 0.7–5.1 |

aPrimary efficacy end-point was the composite of the incidence of any deep vein thrombosis (proximal and/or distal), nonfatal symptomatic, objectively confirmed pulmonary embolism and all cause deaths.
bPrimary safety end-point was the incidence of major bleeding (according to preset criteria) starting after the first postoperative dose of study drug, but no later than 2 days after the last dose of study drug.
cStarted 6–8 h after surgery (tablets).
dStarted on the evening before surgery (injected subcutaneously).
eStarted 12–24 h after surgery (injected subcutaneously).

Abbreviations: THA, total hip arthroplasty; TKA, total knee arthroplasty; riva, rivaroxaban; enox, enoxaparin.
statistical significance (Table 2). The primary safety end-point was observed in 0.7%–5.1% of patients in the rivaroxaban groups, with a significant dose-dependency, compared with 1.9% in the enoxaparin group. When compared with the safety results of the previous study in THA using twice-daily dosing of rivaroxaban the results did not differ much for total daily doses of 5 mg (0.8% vs 2.3%), 10 mg (0.7% vs 2.2%), 20 mg (4.3% vs 2.3%), and 40 mg (5.1% vs 4.5%) (Eriksson et al 2006a). Thus, once-daily dosing of rivaroxaban did not seem to increase the risk of bleeding compared with twice-daily dosing.

In the entire phase II program all adverse reactions observed in the treatment groups were registered. To follow the liver function repeated measurements of liver aminotransferase levels such as alanine aminotransferase (ALT), aspartate aminotransferase (AST) and bilirubin levels up to 7 days after the last dose of study medication were performed. In the second THA study in phase II (Eriksson et al 2006a) ALT or AST levels >3 times the upper limit of normal (ULN) occurred in 11.2% and 8.8% of patients in the enoxaparin group compared with 3.9%–6.4% and 3.3%–8.3%, respectively, in the rivaroxaban groups. In the phase II TKA study (Turpie et al 2005), elevated levels of ALT and AST (>3x ULN) and of bilirubin (2x ULN) were seen in 4 patients in the rivaroxaban groups. Two of these patients with elevated ALT and bilirubin remained on treatment without clinical symptoms. All changes returned to normal at follow-up. In the THA study with once-daily administration of rivaroxaban (Eriksson et al 2006b), ALT or AST levels >3x ULN occurred in 7.1% and 7.1% of patients in the enoxaparin group compared with 3.0%–5.4% and 3.4%–6.2%, respectively, in the rivaroxaban groups. One patient treated with rivaroxaban 30 mg od for 7 days showed elevation of ALT >3x ULN and bilirubin >2x ULN 3 h after the first drug administration. Both returned to normal at follow-up despite continued treatment. In a patient treated with rivaroxaban 10 mg od for 7 days, who eventually had a diagnosis of cholecystolithiasis, liver enzymes continued to rise after treatment cessation. In general, none of the studies showed any dose-dependency between rivaroxaban and increased liver parameters. Based on the findings in the phase II program, however, it was not possible to determine whether there was a relationship between rivaroxaban and liver function impairment. Another open question after the phase II program was whether there was an increased risk of liver function impairment when rivaroxaban was given for thromboprophylaxis on an extended basis (up to 35 days), which was seen with ximelagatran (Kenne et al 2008).

### Rationale for dose selection

In general, when a dose of any new anticoagulant has to be selected both efficacy and safety should be taken into consideration and a perfect balance is preferable. A population analysis was performed to compare the pharmacodynamics and pharmacokinetics of total daily doses of rivaroxaban of 5 mg, 10 mg, and 20 mg (Mueck et al 2006) using blood samples collected in the previously mentioned clinical phase II studies with once- or twice-daily dosing of rivaroxaban in patients undergoing THA (Eriksson et al 2006a, b). It was found that both maximum and minimum plasma concentrations of rivaroxaban were lower after once-daily compared with twice-daily administration, but with overlapping 90% confidence intervals. The pharmacokinetic properties of rivaroxaban were found to be independent of the dosing regimen (Mueck et al 2006). In a blinded, placebo-controlled study in healthy volunteers, the effect of body weight (BW) and gender on the efficacy and safety of a single 10 mg dose of rivaroxaban were assessed. The study showed no influence of extreme BW (> 120 kg) compared with normal BW (70–80 kg) on the C\textsubscript{max} of rivaroxaban, but it was increased by 24% in female subjects weighing 50 kg or less, resulting in a 15% prolongation of PT; however, this result had no clinical relevance. In addition, because gender or BW did not affect the area under the curve, dose adjustment would not be necessary (Kubitza et al 2007b). Based on the rates of the primary safety end-point in the last phase II study, it was obvious that total daily rivaroxaban doses of 5–10 mg were comparable to those seen in the enoxaparin group, 0.7% and 0.8%, respectively, vs 1.9%. On the contrary, the rates of the primary efficacy end-point in these two rivaroxaban groups were clearly lower compared with enoxaparin, 14.9 and 10.6, respectively vs 25.2% (Table 2) (Eriksson 2006b). Summarizing these results, it was decided that a once-daily dosage of 10 mg of rivaroxaban should be studied in the phase III program in orthopedic surgery.

### Phase III program

The clinical phase III program in orthopedic surgery was given the acronym: RECORD (\textit{R}egulation of \textit{C}oagulation in \textit{m}ajor \textit{O}rthopaedic surgery reducing the \textit{R}isk of \textit{D}VT and \textit{PE}). The RECORD program consists of the four clinical prophylaxis studies presented in Table 3. All studies were prospective, double blind, randomized studies comparing the antithrombotic efficacy and safety of rivaroxaban 10 mg given orally once daily and enoxaparin 40 mg once daily or 30 mg twice daily in patients undergoing THA or TKA. RECORD 1 and RECORD 2 were performed in THA...
patients and 40 mg once daily of enoxaparin was used for comparison in both studies. In RECORD 1 both prophylactic regimens were given for a total duration of 35 ± 4 days (long term), whereas in RECORD 2 only rivaroxaban was given long term compared with enoxaparin which was given for 10–14 days (short term) (Table 3), because it is not universally accepted to use long-term prophylaxis after THA in spite of the recommendation in the ACCP guidelines (Geerts et al 2004). RECORD 3 and RECORD 4 were performed in TKA patients with short-term duration (10–14 days) of both regimens, because long-term prophylaxis is not recommended after TKA (Geerts et al 2004). In RECORD 3, 10 mg of rivaroxaban once daily started 6–8 h after surgery was compared with 40 mg of enoxaparin started in the evening before surgery, whereas in RECORD 4 enoxaparin 30 mg twice daily started 12–24 h after surgery was used in the comparator arm (Table 3). The efficacy results of the RECORD studies are presented in Tables 4 and 5. In all studies rivaroxaban was significantly more effective in reducing the primary efficacy end-point, the composite of the incidence of any DVT (proximal and/or distal), nonfatal symptomatic, objectively confirmed PE and all cause deaths and major VTE, the composite of proximal DVT, PE, and VTE-related death, compared with enoxaparin (Table 4). In the RECORD 2 and RECORD 3 studies, rivaroxaban also significantly reduced the incidence of symptomatic VTE events compared with enoxaparin (Table 5), which are important clinical observations. The safety (the incidence of major and/or minor bleeding events) of rivaroxaban was comparable with enoxaparin in all the phase III studies (Table 6). The RECORD 4 study has been finalized very recently, but no results have been released yet. The liver safety parameters showed no important differences between rivaroxaban and enoxaparin, and no different action was observed on liver function when rivaroxaban was used for long-term prophylaxis in the RECORD 1 and RECORD 2 studies compared with short-term prophylaxis with rivaroxaban. A more detailed description of these results cannot be given because the studies have been published only in abstract form.

**Patient-focused perspectives such as quality of life, patient satisfaction/acceptability**

The ideal antithrombotic is a drug with a broad therapeutic window in terms of efficacy versus safety (bleeding), with a rapid onset and offset of action, with a high bioavailability and minimal food and drug interactions after oral administration, and predictable pharmacodynamics and pharmacokinetics with

no requirement for dose adjustment and coagulation monitoring. For the patient, such a drug would be easy to handle in everyday life, and therefore patient acceptability would be easily obtained. When we consider the clinical behavior of rivaroxaban in phase II and III it seems that it comes close to this ideal. However, there are still some outstanding questions to be resolved, such as the influence of impaired renal function on drug safety, the lack of an antidote in case of a bleeding event, and patients with nausea and vomiting after surgery being unable to take the medication as planned, and patients with indwelling epidural catheters. Based on previous experience, the cost-effectiveness of a new drug compared with existing alternatives is also important for clinicians deciding whether to use a new drug. Competition from other new drugs on the market is also important. Dabigatran etexilate, an oral direct thrombin inhibitor, has recently been approved in Europe for thromboprophylaxis in orthopedic settings. In a recent prospective study, dabigatran etexilate was as effective and safe as enoxaparin 40 mg od in reducing the risk of VTE after THA (Eriksson et al 2007d). Within the near future it will be settled if both drugs will be approved and then only a direct comparison in a relevant clinical study can show which of the drugs that has the most profitable efficacy and safety.

Conclusions, therapeutic potential

Rivaroxaban – an oral, direct FXa inhibitor – is a new compound for VTE prophylaxis after orthopedic surgery. The drug has predictable pharmacokinetics and pharmacodynamics and needs no coagulation monitoring or dose adjustment. Results from phase II and phase III clinical studies have shown that rivaroxaban, at a once-daily dosage of 10 mg, has a significantly better efficacy and a comparable safety compared with enoxaparin in patients undergoing THA and TKA.
