Background: Chemokines have been identified to be involved in the modulation of pain through both peripheral and central mechanisms. However, the role of chemokines in lumbar disk herniation (LDH) with sciatic pain remains unknown.

Objective: The current study was performed to explore the expression of two most commonly studied chemokines CX3CL1 and CCL2 and assess their associations with clinical severity in LDH patients with sciatic pain.

Methods: The soft tissues around nerve root (STANR), annulus fibrosus (AF), and nucleus pulposus (NP) biopsies were obtained from 36 LDH patients with chronic sciatic pain and 10 scoliosis patients (painless controls). The serum and local expressions of CX3CL1 and CCL2 were determined using enzyme-linked immunosorbent assay and Western blot analysis, respectively. The visual analog scale (VAS) scores for low back pain and lower extremity pain and Japanese Orthopaedic Association (JOA) scores were recorded on the day of hospital admission to evaluate the clinical severity. LDH patients with sciatic pain were divided into severe pain (SP) group (VAS ≥ 7 ; n=18) and mild-to-moderate pain (M-MP) group (VAS < 7 ; n=18) for lower extremity pain.

Results: Local expressions instead of CX3CL1 and CCL2 in STANR, AF, and NP were significantly higher in the SP group than in M-MP compared with scoliosis painless group. Expressions of both CX3CL1 and CCL2 in STANR and AF were positively correlated with VAS scores for lower extremity and for low back pain, respectively. In addition, CX3CL1 and CCL2 expressions in STANR were negatively associated with JOA scores. There were no significant differences of serum CX3CL1 and CCL2 levels among SP group, M-MP group, and scoliosis painless group.

Conclusion: Both CX3CL1 and CCL2 may play important roles in maintaining pain in LDH patients. Local blockade of CX3CL1 and CCL2 in LDH patients with persistent pain deserves further intensive study.

Keywords: lumbar disk herniation, sciatic pain, CX3CL1, CCL2

Introduction

Lumbar disk herniation (LDH) is one of the most common spinal degenerative disorders that frequently affects the spine in young and middle-aged adults.¹ The clinical consequences of LDH physiology are spinal pain and stiffness, prolapse with nerve root pain, and stenosis with spinal claudication.² Pain is the most common complaint in LDH patients. Pain in LDH is present either local to the disordered disk or in the lower limb with associated paresthesiae caused by root compression and spinal stenosis.³

In the past, pain in patients with disk diseases including LDH has long been attributed to the pressure put on the sciatic nerve root by the herniated disk. However,

advances in basic and clinical study have clarified the fact that production of pain in LDH is not only due to mechanic pressure but is also due to a significant contribution by chemical factors.⁴ This conclusion is based on the following clinical observations. 1) Disk surgery does not always release pain; 2) large disk herniations are not always symptomatic; 3) severe pain (SP) may be present in patients without imaging evidence of nerve root compression; 4) the severity of symptoms and neurological signs is not well related to the size of the disk herniation; and 5) conservative therapy is often effective.⁵⁻⁸

Recent basic studies have strengthened the potential role for autoimmunity in the progression of LDH. The disk-derived cells are able to secrete pro-inflammatory cytokines without inflammatory cells, supporting the hypothesis that disk-derived cells have the capacity of initiating as well as amplifying the inflammatory process.⁹ Furthermore, infiltration and activation of various immune cells contribute to amplification of an inflammatory response and the release of neurotrophic factors that aggravate reinnervation of the disk or nerve sensitization of spinal nerves.^{10,11}

Chemokines constitute of a group of pro-inflammatory cytokines with potent chemotactic activities for leukocytes both in vitro and in vivo.¹² Chemokines are classified into four groups (CC, XC, CXC, and CX3C) based on the number and position of conserved cysteine residues in their amino acid structure, and their receptors are accordingly designated as CCR, XCR, CXCR, or CX3CR.¹³ The chemokines act both at the initial and later stages of inflammatory response and draw inflammatory cells from blood into tissues.¹⁴

Among the chemokines, the CX3C and CC subfamilies are most widely studied. Specifically, CX3CL1 (C-X3-C motif ligand 1), also named as fractalkine, is structurally unique among the family of chemokines and their receptors and is expressed both in the central nervous system and peripheral nerves, as well as in endothelial cells and lymphocytes. CCL2 (C-C motif ligand 2), also known as monocytes chemoattractant protein-1, is a chemokine that has been demonstrated to play a critical role in chronic pain facilitation via CCR2. CCL2 and CX3CL1 signaling through CCR2 and CX3CR1 have been shown to be key factors in the recruitment of inflammation cells to tissue lesions or sites of inflammation,¹⁵ and so are key factors in persistence of neuropathic pain.^{16,17}

A previous study has shown that chemokine (including CX3CL1 and CCL2) production by herniated intervertebral disk tissue is the reason for the generation and maintenance of surrounding inflammation.¹⁸ Park et al¹⁹ found that

CX3CL1 immunoreactivity gradually increased in laminae II and III of the ipsilateral dorsal horn by using a nucleus pulposus (NP) implantation-induced model of LDH. One recent study showed that CCL2/CCR2 signaling in the dorsal root ganglion and spinal cord plays a significant role in the maintenance of neuropathic pain in a rat model of LDH.²⁰

All these works implicated that CCL2 and CX3CL1 may both play important roles in pain maintenance and aggravation in LDH patients. To our knowledge, most of the studies in this area were carried out on animal models, and there were no studies available illustrating the relationship between systemic and local chemokine expressions and clinical severity in LDH patients. Therefore, we aimed to investigate the potential mechanism from the biochemical aspects by exploring expressions of CCL2 and CX3CL1 in LDH patients and by assessing their association with clinical severity.

Methods

Study patients and clinical assessment

This study was approved by the Ethics Committee at Chenzhou No. 1 People's Hospital, Hunan, People's Republic of China. Thirty-six patients diagnosed as having LDH with sciatic pain were enrolled at the Department of Spinal Orthopedics. The clinical inclusion criteria are as follows: 1) low back pain with radiation to the lower limb; 2) radicular pain along a specific dermatome; 3) nerve root tension signs like straight leg raising test; and 4) presence of neurological symptoms and signs. Diagnosis of LDH was further confirmed using magnetic resonance imaging. Also, ten scoliosis patients without signs of pain or degenerative disk disease were selected as controls. Written informed consent was obtained from all the patients (or from their parents if they were under the age of 16 years).

The soft tissues around nerve root (STANR), annulus fibrosus (AF), and NP biopsies were obtained intraoperatively from 36 LDH patients with chronic sciatic pain during discectomy and were obtained from ten scoliosis patients (painless controls) during corrective orthopedic surgery.

Assessment of serum CX3CL1 and CCL2 levels

About 10 mL of blood sample was collected from each patient in the morning and then centrifuged at 3,000 rpm for 10 min. The obtained serum was then stored at -80°C until use. Serum CX3CL1 and CCL2 levels were measured using the enzyme-linked immunosorbent assay technique (Santa Cruz Biotechnologies, Inc., Santa Cruz, CA, USA). Intra-assay

coefficients of variability were 4.1% and 4.4%, respectively, and the interassay coefficients of variability were less than 6%.

Local CX3CL1 and CCL2 protein expressions explored using Western blot analysis

Tissue samples from STANR, AF, and NP were rapidly removed and stored at -80°C until use. All tissue samples were homogenized in lysis buffer containing phenylmethane sulfonyl fluoride and 0.02% protease inhibitor cocktail. The homogenates were centrifuged at $14,000\times g$ for 15 min at 4°C . Equivalent amounts of protein (40 μg) were separated using 10% sodium dodecyl sulfate–polyacrylamide gel electrophoresis and transferred onto a polyvinylidene difluoride membrane. Membranes were blocked with 5% milk for 1 h at room temperature and incubated with respective primary antibodies anti-CX3CL1 (1:1,000; Santa Cruz Biotechnologies, Inc) and anti-CCL2 (1:4,000; Abcam, Cambridge, UK) overnight at 4°C . The membranes were incubated for 1 h with horseradish peroxidase-conjugated secondary antibody (1:5,000; Santa Cruz Biotechnologies, Inc). Bands were finally revealed using an enhanced chemiluminescence kit (Kodak, Rochester, NY, USA). The monoclonal antibody against β -actin (1:10,000; Sigma-Aldrich Co., St Louis, MO, USA) was used as a loading control. Bands area/intensity for all proteins were measured using Image J software (Wayne Rasband; National Institutes of Health, Bethesda, MD, USA). All the samples were routinely analyzed using Western blot repeated for at least three times, and the obtained results were averaged and calculated.

Pain and function assessment

The visual analog scale (VAS) was administered to evaluate the degree of pain, ranging from 0 to 10, where 0 indicates complete satisfaction or no pain at all, whereas 10 indicates complete dissatisfaction or maximum pain. Here, we recorded VAS scores for both lower extremity pain and low back pain.

LDH patients with sciatic pain were divided into SP group (VAS ≥ 7 ; $n=18$) and mild-to-moderate pain (M-MP) group (VAS < 7 ; $n=18$) for lower extremity pain. Japanese Orthopedic Association (JOA) scores were utilized to assess the comprehensive functional status in patients. The JOA score system is a widely used clinical evaluation scoring system for low back pain syndrome including subjective symptoms, clinical signs, restriction of activities of daily living, and urinary bladder function, ranging from 0 to 29 points, where higher scores represent less pain and better function and lower scores indicate SP and worse function. The JOA score system is a validated instrument designed specifically for the assessment of patients with low back pain and worse function. JOA score is widely used based on the clinical evidence and experience.²¹

Statistical analysis

Statistical analysis was performed using the Statistical Package for Social Sciences 21.0 statistical software (IBM, Armonk, NY, USA). Data were presented as mean $\pm$ standard deviation or median (interquartile range). Data normality was analyzed using the Kolmogorov–Smirnov test. The one-way analysis of variance or Kruskal–Wallis test was applied to test statistically significant differences in protein expression between SP and M-MP LDH patient groups as well as the scoliosis control group, followed by a Dunn's post hoc test. The Spearman's or Pearson's correlation analysis was used to examine the association of CX3CL1 or CCL2 level with VAS as well as JOA scores. Probability values or differences < 0.05 were considered to be statistically significant.

Results

Baseline clinical characteristics

With the exception of significant difference in age ($P < 0.001$), no significant differences were observed in indices of sex ratio, disease duration, body mass index, and serum CX3CL1 and CCL2 levels among the three groups. The basic clinical and laboratory characteristics are listed in Table 1.

Table 1 Baseline clinical characteristics

	SP	M-MP	Con	P-value
N	18	18	10	NS
Sex (female/male)	7/11	9/9	5/5	NS
Age (years)	34.2 $\pm$ 5.8	33.3 $\pm$ 6.8	22.1 $\pm$ 4.1	< 0.001
Disease duration (months)	4.5 (1–22)	5.2 (2–18)	72 (36–96)	–
BMI (kg/m^2)	22.69 (18.15–24.53)	23.12 (18.33–25.01)	21.58 (17.68–24.72)	NS
Serum CX3CL1 levels (pg/mL)	120.8 $\pm$ 14.4	112.8 $\pm$ 15.5	113.6 $\pm$ 11.4	NS
Serum CCL2 levels (pg/mL)	94.2 $\pm$ 10.5	90.7 $\pm$ 10.8	85.1 $\pm$ 12.9	NS

Abbreviations: SP, severe pain; M-MP, mild-to-moderate pain; Con, scoliosis painless control; NS, not significant; BMI, body mass index.

Serum and local CX3CL1 and CCL2 expressions in LDH patients and controls

According to the extent of pain, LDH patients with sciatic pain were divided into SP group (VAS ≥ 7 ; $n=18$) and M-MP group (VAS < 7 ; $n=18$). In addition, ten scoliosis painless controls were selected as nonpainful controls. No significant differences were found both in serum CX3CL1 and CCL2 levels among SP LDH patients, M-MP LDH patients, and scoliosis painless controls (CX3CL1: 120.8 ± 14.4 pg/mL vs 112.8 ± 15.5 pg/mL vs 113.6 ± 11.4 pg/mL, $P>0.05$; CCL2: 94.2 ± 10.5 pg/mL vs 90.7 ± 10.8 pg/mL vs 85.1 ± 12.9 pg/mL) (Table 1; Figure S1A and B). Both STANR, NP, and AF CX3CL1 and CCL2 protein expressions in SP and M-MP groups were significantly higher than those in the

scoliosis painless control group (All $P<0.05$; Figures 1 and 2A–E). We further compared the local CX3CL1 and CCL2 expressions between SP and M-MP groups. We found only the STANR CX3CL1 but not CCL2 expressions were significantly higher in SP group compared with M-MP group ($P=0.02$; Figure 2A). However, interestingly, NP but not STANR CCL2 expression was higher in SP group compared with M-MP group ($P=0.04$; Figures 1 and 2E).

Association of local CX3CL1 and CCL2 protein expression levels with VAS and JOA scores

The associations of CX3CL1 and CCL2 protein expression levels in STANR, AF, and NP with VAS scores as well as

Figure 1 CX3CL1 and CCL2 band expressions were determined using Western blot analysis among three groups.

Notes: Expression levels were normalized to β -actin as house-keeper factor.

Abbreviations: STANR, soft tissues around nerve root; SP, severe pain; M-MP, mild-to-moderate pain; Con, scoliosis painless control; AF, annulus fibrosus; NP, nucleus pulposus.

Figure 2 Quantification analysis of CX3CL1 and CCL2 protein expressions among three groups.

Notes: Expression levels were normalized to β -actin as house-keeper factor and are represented as time-fold increase compared with controls. (A–C) CX3CL1 protein expressions among three groups in STANR (A), NP (B), and AF (C). (D–F) CCL2 protein expressions among three groups in STANR (D), NP (E), and AF (F). ** $P<0.01$.

Abbreviations: SP, severe pain; M-MP, mild-to-moderate pain; Con, scoliosis painless control; NS, not significant; AF, annulus fibrosus; NP, nucleus pulposus; STANR, soft tissues around nerve root.

JOA scores of patients with LDH were explored. Correlation analysis showed that only STANR CX3CL1 and CCL2 protein expression levels in patients were positively correlated with VAS (CX3CL1: $r=0.393$, $P=0.018$ and CCL2: $r=0.360$, $P=0.03$) for lower extremity pain (Figure 3A–F) and negatively related to JOA scores (CX3CL1: $r=-0.342$,

$P=0.04$ and CCL2: $r=-0.375$, $P=0.02$; Figure 4A–F). In addition, CX3CL1 and CCL2 protein expression levels in AF (Figure 5C and F) instead of STANR (Figure 5A and D) were also positively correlated with VAS for low back pain (CX3CL1: $r=0.349$, $P=0.04$ and CCL2: $r=0.365$, $P=0.03$). However, correlations of CX3CL1 and CCL2 protein

Figure 4 Correlation of local CX3CL1 (A–C) and CCL2 (D–F) expressions with JOA scores.

Notes: (A–C) Correlation of CX3CL1 protein expressions with JOA scores in STANR (A), NP (B), and AF (C), respectively. (D–F) Correlation of CCL2 protein expressions with JOA scores in STANR (D), NP (E), and AF (F), respectively.

Abbreviations: AF, annulus fibrosus; NP, nucleus pulposus; JOA, Japanese Orthopedic Association; STANR, soft tissues around nerve root.

Figure 5 Correlation of local CX3CL1 and CCL2 expressions with VAS scores (in centimeters) for low back pain.

Notes: (A–C) Correlation of CX3CL1 protein expressions with VAS scores for low back pain in STANR (A), NP (B), and AF (C), respectively. (D–F) Correlation of CCL2 protein expressions with VAS scores for low back pain in STANR (D), NP (E), and AF (F), respectively.

Abbreviations: SP, severe pain; STANR, soft tissues around nerve root; AF, annulus fibrosus; NP, nucleus pulposus; VAS, visual analog scale.

expression levels in NP with VAS and JOA did not reach significant differences (all $P>0.05$; Figure 3B and E; Figure 5B and E; Figure 4B and E).

Discussion

This study was performed to examine the local and circulating levels of the most widely studied chemokines CX3CL1 and CCL2 in LDH patients with radicular pain. To our knowledge, this is the first time that we explored CX3CL1 and CCL2 expressions in LDH patients. Our findings demonstrated that the local expressions instead of serum levels of CX3CL1 and CCL2 are significantly higher in LDH patients compared with controls. In addition, we also investigated the relationship of the two chemokines and disease severity defined by the degree of pain and functional disability. We observed that both CX3CL1 and CCL2 expressions are significantly associated with more serious pain and worse function. These findings implicated that local CX3CL1 and CCL2 play potential roles in the progression and aggravation of the disease.

LDH, which is manifested by low back pain or sciatica, is one of the common causes of disability in the community. The reported lifetime occurrence of LDH achieves as high as 40%.²² In LDH, NP material exits the disk space area through the AF, causing mild compression on the spinal nerves and resulting in neurological dysfunction including pain, sensory deficits, and weakness in the low back and leg.²³ In recent years, a growing number of works have identified the role of

inflammation and immune activation in the pathogenesis of lumbar disk disease. Cytokines including interleukin (IL)-1 and tumor necrosis factor (TNF)- α are found to be elevated in LDH patients with or without sciatic pain.^{24,25} It has also been proved that LDH patients with chronic pain had higher levels of TNF- α , IL-1, and IL-6 than controls,^{26,27} thus supporting the role of inflammation on aggravation and maintenance of pain.

As one important family of cytokines, chemokines in recent years have been shown to play a pivotal role in the induction and maintenance of inflammation and chronic pain.²⁸ The best known chemokines in pain are CX3CL1 and CCL2, which signal through their designated receptors. Local expressions of CX3CL1 and CCL2 in STANR, AF, and NP were all significantly higher in the SP group than in M-MP compared with scoliosis painless group. However, we found that serum CX3CL1 and CCL2 levels between LDH patients and control subjects did not reach significant difference, implicating that inflammation or pain in LDH is more like a local process rather than systemic activity. We further found both expressions of CX3CL1 and CCL2 in STANR and AF were positively correlated with VAS scores for lower extremity pain and low back pain, respectively. However, only the local expressions of both the chemokines in AF negatively associated with JOA scores. This may be attributed to the fact that pain in lower extremity and low back were generated by different nerves. The former is generated by sinuvertebral nerve and the latter is produced by sciatic nerve. The sciatic

nerve has much more fibers than the sinuvertebral nerve and is more sensitive to pain. These results above both implicated that CX3CL1 and CCL2 may play important roles in the nerve root inflammation and neuropathic pain.

CX3CL1/CX3CR1 mediates neuron–microglial communication in chronic pain states and is therefore key to the development of neuropathic pain.²⁹ In addition, peripheral inflammation-induced hypernociception is accompanied and mediated by satellite glial cells activation. Souza et al³⁰ found that CX3CL1/CX3CR1 signaling in the dorsal root ganglion plays a key role in the peripheral inflammation and the activation of satellite glial cells, and they conclude this process is crucial to the induction/maintenance of inflammatory pain. Oh et al³¹ evaluated the expression of CX3CL1 and CX3CR1 in patients with cervical and LDH to clarify their roles in the disk degeneration. They found greater CX3CL1/CX3CR1 mRNA/CX3CR1-positive cells expression in cervical herniated NP patients than in lumbar herniated NP patients using reverse transcription polymerase chain reaction and histologic and immunohistochemical analysis. However, references of symptoms including pain and function were not recorded. Therefore, we speculate that CX3CL1 and CX3CR1 would exhibit higher expressions when pain symptoms are present.

CCL2 is another well-known chemokine amplifying and maintaining inflammation through chemokine–cytokine networks following the recruitment of circulating leukocytes. Zhu et al³² found that LDH could induce overexpression of CCL2 in NP cells. And, elevated CCL2 expression has been also detected in LDH animal models and human degenerated disks.³³ Several studies have also shown that CCL2 is involved in the activation of spinal microglia associated with neuropathic pain,^{34,35} which can result in central sensitization by the release of a series of modulators, which enhances pain states further.

Low back pain in LDH patients is believed to originate from internal disk disruptions and is mainly mediated by the sinuvertebral nerve.³⁶ Here, we also found that elevated CX3CL1 and CCL2 expressions in AF instead of NP were positively associated with low back pain. This may be attributed to free sinuvertebral nerve endings that are mainly distributed in the superficial area of AF, but not in NP and deeper zones of AF.³⁷

Some limitations should be taken into account in the present study. First, this study was performed only in Chinese people, and the sample size enrolled was not large enough, thus leading to limited statistical power. Therefore, multicenter studies with a large sample size are further needed to identify the present results. Second, we only focused the investigation of CX3CL1 and CCL2, examination of

other inflammatory markers such as IL-1 and TNF- α may be more powerful and meaningful to illustrate their roles in LDH inflammation. Finally, we were not able to examine the systemic and local CX3CL1 and CCL2 expression levels due to ethical reasons, failing to get the information about the alternation of CX3CL1 and CCL2 expression following symptomatic relief.

Conclusion

In summary, local instead of serum CX3CL1 and CCL2 protein expressions in LDH patients with sciatic pain were higher than in scoliosis painless control. In addition, local expressions of CX3CL1 and CCL2 in STANR were positively correlated with SP and worse function. Local CX3CL1 and CCL2 protein expressions may reflect clinical severity in LDH patients with sciatic pain. Local expressions of CX3CL1 and CCL2 have the potential to serve as targets for adjunctive treatment of LDH combined with other therapies, but the clinical applications need intensive study in the future.

Supplementary material

Figure S1 Investigation of serum CX3CL1 (A) and CCL2 (B) among three groups.

Abbreviations: SP, severe pain; M-MP, mild-to-moderate pain; Con, scoliosis painless control; NS, not significant.

Journal of Pain Research

Publish your work in this journal

The Journal of Pain Research is an international, peer reviewed, open access, online journal that welcomes laboratory and clinical findings in the fields of pain research and the prevention and management of pain. Original research, reviews, symposium reports, hypothesis formation and commentaries are all considered for publication.

Submit your manuscript here: <https://www.dovepress.com/journal-of-pain-research-journal>

Dovepress

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
