Background: Compound porcine cerebroside and ganglioside injection (CPCGI) is a neurotrophic drug used clinically to treat certain functional disorders of brain. Despite its extensive usage throughout China, the exact mechanistic targets of CPCGI are unknown. This study was carried out to investigate the protective effect of CPCGI against ischemic neuronal damage in rats with middle cerebral artery occlusion (MCAO) reperfusion injury and to investigate the neuroprotective mechanisms of CPCGI.

Materials and methods: Adult male Sprague-Dawley rats were subjected to MCAO surgery for 2 hours followed by reperfusion. The rats were administered CPCGI once a day for 14 days after reperfusion, and behavioral tests were performed 1, 3, 7, and 14 days post MCAO. Hematoxylin–eosin staining was used to measure infarct volume, and immunohistochemical analysis was performed to determine the number of NeuN-positive neurons in the ischemic cortex penumbra. Finally, the relative expression levels of proteins associated with apoptosis (Bcl-2, Bax, and GADD45 α), synaptic function (Synaptophysin, SNAP25, Syntaxin, and Complexin-1/2), and mitochondrial function (KIFC2 and UCP3) were determined by Western blot.

Results: CPCGI treatment reduced infarct size, decreased neurological deficit scores, and accelerated the recovery of somatosensory function 14 days after MCAO. In addition, CPCGI reduced the loss of NeuN-positive cells in the ischemic cortex penumbra. In the ischemic cortex, CPCGI treatment decreased GADD45 α expression, increased the Bcl-2/Bax ratio, augmented Synaptophysin, SNAP25, and Complexin-1/2 expression, and increased the expression of KIFC2 and UCP3 compared with sham rats 14 days after MCAO reperfusion injury.

Conclusion: CPCGI displays neuroprotective properties in rats subjected to MCAO injury by inhibiting apoptosis and improving synaptic and mitochondrial function.

Keywords: compound porcine cerebroside and ganglioside injection, cerebral ischemia reperfusion, multitarget, neuroprotection

Introduction

Tissue plasminogen activator is the only clinically approved therapy to treat the early onset of ischemic stroke;^{1–3} hence, many researchers have attempted to develop novel neuroprotective therapeutics. Despite encouraging preclinical testing, currently there remain no drugs that result in consistent clinical improvements,^{4,5} possibly due to the highly complex pathophysiologic responses that occur in brain during stroke. It is well known that ischemia is a complex process that finally leads to neuronal death via multiple pathways including apoptosis, necrosis, inflammation, immune modulation, oxidative stress,

excitotoxicity, and mitochondrial dysfunction.^{6–8} Therefore, a paradigm has emerged whereby the development of novel therapeutics now includes the identification of multifunctional drugs that can target a variety of biological pathways.⁹

Compound porcine cerebroside and ganglioside injection (CPCGI, drug approval H22026472; Buchang Pharmaceutical Group Ltd., Jilin, China), which was approved by the China Food and Drug Administration in 2010, is widely used in China for the treatment of stroke, Alzheimer's disease, central and peripheral nerve injuries, and functional disorders caused by diseases related to the brain. Each milliliter of CPCGI is estimated to contain ~50 µg of gangliosides (GM-1), 3.2 mg of polypeptides, and 0.25 mg of hypoxanthine. The active ingredients of CPCGI, GM-1 and carnosine, have been reported to possess significant therapeutic potency with respect to the treatment of ischemic stroke.^{10,11} GM-1 acts as a neurotrophic factor in the central nervous system,¹² promoting survival, differentiation, neurodegeneration, axon stability, and regeneration in both injured and aging brains.^{13–16} In addition, carnosine, a dipeptide composed of β-alanine and histidine, protects against neurological damage in both permanent and transient cerebral ischemia models by modulating multiple cellular processes including oxidative stress, apoptosis, excitotoxicity, and autophagy with no apparent toxicity or side effects.^{17–21} However, the role of CPCGI in cerebral ischemia–reperfusion has not yet been described.

In the present study, the neuroprotective effects of CPCGI were assessed in a rat model of middle cerebral artery occlusion (MCAO). Furthermore, the study attempted to discern the molecular mechanism, whereby CPCGI treatment exhibits a multitargeted effect on ischemia–reperfusion.

Materials and methods

Animals

All in vivo experiments were conducted in accordance with the guidelines established by the National Institutes of Health for the care and the use of laboratory animals and approved by the Animal Care Committee of the Peking Union Medical College and Chinese Academy of Medical Sciences. Adult male Sprague-Dawley rats weighing 250–270 g were purchased from the Academy of Military Medical Sciences (Beijing, China). Before surgery, the rats were acclimated for 1 week and housed in a temperature-controlled environment with a 12-hour light/dark cycle and ad libitum access to food and water.

Cerebral ischemia–reperfusion model

The MCAO surgery was conducted as previously described with several modifications.^{22,23} All rats were anesthetized

with 1% pentobarbital sodium (50 mg/kg) by intraperitoneal injection followed by the insertion of an intraluminal suture from the external carotid artery stump into the internal carotid artery for 2 hours. The suture was then withdrawn to recover blood circulation. After the surgery, all animals were kept warm before regaining consciousness. The rats of the sham group underwent the same procedure without the ligation of arteries. Animals were then randomly assigned into 5 groups (n=10): sham, model, CPCGI-low (L) (0.5 mL/kg/d), CPCGI-high (H) (1 mL/kg/d), and Ginaton (50 mg/kg/d, as positive control) groups.^{24,25} CPCGI was obtained from the Jilin Buchang Pharmaceutical Group Co., Ltd (Jilin, People's Republic of China). Ginaton injection solution was purchased from the Chi Sheng Chemical Corporation (Taiwan, China). Vehicle, CPCGI, or Ginaton were injected intraperitoneally from the start of reperfusion once a day for 14 days until the animals were killed. Sham and model groups received an equivalent volume of saline.

Neurological function assessment

For all animals, a blind neurological function assessment was performed 1, 3, 7, and 14 days after MCAO. Neurological deficits were evaluated, as previously described, by a set of modified Neurological Severity Scores (NSS) tests, involving a series of motor, sensory, reflex, and balance measurements.^{26,27} Using the NSS test, neurological function was graded from 0 to 18 (normal score =0; maximal deficit score =18).

Adhesive removal test

Adhesive removal tests were carried out 14 days after MCAO, as described previously, with several modifications.²⁶ In brief, two small pieces of adhesive backed paper dots of equal size (100 mm²) were used as bilateral tactile stimuli occupying the distal–radial region on the wrist of each forelimb. After adhesion of the paper dots, the rats were then placed into hyaline cages for observation. The time taken by the rats to remove the stimulus from the forelimbs was recorded. Before the adhesive removal test, the rats were trained to familiarize themselves with their environment. The maximal time allowed for each test was 2 minutes.

Tissue preparation

Fourteen days after MCAO, rats (n=6 for each group) were anesthetized with 1% pentobarbital sodium (50 mg/kg) intraperitoneally and perfused first with 0.1 mol/L phosphate-buffered saline (PBS) and then 4% paraformaldehyde (pH 7.4) through the left ventricle. The brains were harvested and fixed in 4% paraformaldehyde solution at 4°C, followed by achievement of equilibrium with 0.1 mol/L PBS

containing 15%, 20%, and 30% sucrose at 4°C, respectively. Each brain was coronally sectioned (2-mm thick), from frontal to occipital pole, into five segments. Coronal sections were then prepared for hematoxylin–eosin (HE) staining (10-μm thick) and immunohistochemical analysis (35-μm thick) using a cryostat.

Infarct volume assessment

One coronal section from each segment described earlier was stained with HE to measure the infarct volume.²⁸ The sections were photographed by using a digital camera and analyzed by Image-Pro Plus 6.0. The infarct volumes of the lesion structures were expressed as a percentage of the volume of the structures from the control hemispheres by using the formula $[(V_c - V_L)/V_c] \times 100\%$, where V_c is the volume of control hemisphere and V_L is the volume of noninfarcted tissue in the lesion hemisphere.²⁹ The total infarct volume of each brain was calculated as the sum of the infarct volumes of the five brain slides.

Immunohistochemical analysis

Immunohistochemical analysis was performed as previously described.²³ Briefly, brain slices were taken 0.20–1.00 mm rostral from the bregma (motor cortex and primary somatosensory cortex, forelimb region) followed by three washes with PBS and incubation in 3% H₂O₂ solution for 10 minutes to reduce endogenous peroxidase activity. After another three washes with phosphate-buffered saline-Triton 100 (PBST), the slices were blocked in 10% bovine serum for 1 hour and incubated overnight with a mouse anti-NeuN antibody (1:400; Merck Millipore, Darmstadt, Germany) at 4°C. The slides were washed another three times with PBS, then incubated with a horseradish peroxidase (HRP) goat anti-mouse secondary antibody per the manufacturer's instructions (Beijing Zhong Shan Biotechnology Co., Beijing, China). The slices were then visualized using a 3',3'-diaminobenzidine (DAB) substrate kit (Xi Ya Jin Qiao Biological Technology, Beijing, People's republic of China), and images were captured using a charge coupled device (CCD) camera (Olympus, Tokyo, Japan). The number of NeuN-positive cells was blindly counted for three fields of view evenly distributed throughout the areas of interest by using Image-Pro Plus 6.0 software.

Western blotting

Total proteins were extracted from the ischemic cortex 14 days after MCAO (n=3 for each group). Western blots were performed as previously described.²³ Equal amounts of sample from each group were separated by sodium dodecyl sulfate–polyacrylamide gel electrophoresis and transferred

to polyvinylidene fluoride membranes. The membranes were blocked in 5% nonfat milk for 1 hour at room temperature and then incubated overnight at 4°C with the desired primary antibodies: rabbit anti-GADD45α (1:1,000; CST, Danvers, MA, USA), rabbit anti-Bcl-2 (1:1,000; CST), rabbit anti-Bax (1:1,000; CST), rabbit anti-KIFC2 (1:200; Santa Cruz Biotechnology Inc., Dallas, TX, USA), rabbit anti-SNAP25 (1:1,000; CST), rabbit anti-Syntaxin (1:5,000; Abcam, Cambridge, UK), rabbit anti-Complexin-1/2 (1:1,000; CST), rabbit anti-UCP3 (1:200; Novus, San Jose, CA, USA), and mouse anti-β-actin (1:1,000; Applygen, Beijing, People's republic of China). After washing three times with tris-buffered saline-Tween 20 (TBST), the membranes were incubated with secondary antibodies conjugated to HRP for 1 hour. The immunoblots were visualized with enhanced chemiluminescence and analyzed using GelPro software. For each blot, β-actin served as an internal loading control.

Statistical analysis

All data were analyzed by one-way analysis of variance using Statistical Package for the Social Sciences (SPSS) 17.0 software (SPSS Inc., Chicago, IL, USA). Multiple comparison post hoc tests among groups was performed with the Least-Significant Difference test or Dunnett's post hoc test depending on the homogeneity of variance test. Data were presented as mean values ± standard deviation (SD), and differences between groups were considered significant at $P < 0.05$.

Results

CPCGI protects the rat brain from ischemic damage

We first investigated the neuroprotective effect of CPCGI in rat focal cerebral ischemia. Fourteen days after reperfusion, no cerebral injury was detected in the sham group, whereas the model group showed a significant area of infarct. Treatment with a high dose of CPCGI significantly decreased infarct volumes from 50.5% to 32.9%, and a similar effect was observed with Ginaton treatment in rats subjected to MCAO (Figure 1A and B). It was found that CPCGI improved neurological performance post-MCAO, as measured using the NSS and adhesive removal tests. The rats in the model group showed the highest neurological deficit score, whereas the neurological deficit scores of rats administered CPCGI were significantly lower 14 days after reperfusion compared with the model group (Figure 1C). Rats exposed to a high dose of CPCGI also took a significantly shorter time (48.2 seconds) to remove an adhesive stimulus 14 days after reperfusion compared with the model group (93.5 seconds) (Figure 1D). In addition, treatment with

Figure 1 CPCGI protects against brain injury after cerebral ischemia reperfusion in MCAO rats.

Notes: (A) Representative infarct volume measured by hematoxylin-eosin staining 14 days after reperfusion; (B) quantitative assessment of infarct volume ratios from experimental groups; (C) NSS scores; (D) adhesive removal assessment post-reperfusion. Data are expressed as mean values $\pm$ SD, * $P < 0.001$ versus Sham; # $P < 0.05$, ## $P < 0.01$ versus Model; $n = 8-10$.

CPCGI prevented the loss of NeuN-positive neurons in the ischemic cortex penumbra after reperfusion (Figure 2). Therefore, CPCGI treatment seemed to protect the brain against ischemic damage post-MCAO.

CPCGI abrogates MCAO-induced apoptosis in the ischemic cortex

Apoptosis is the primary biological process that drives neuronal cell death after ischemia.³⁰ It has previously been shown that carnosine, one of the main components of CPCGI, plays an important role in inhibiting neuronal apoptosis after acute cerebral ischemia.^{20,31} To determine the role of apoptosis in CPCGI-mediated neuroprotection, the levels of apoptosis-related proteins (Bcl-2, Bax, and GADD45 α) were measured in the ischemic cortex by Western blot. After reperfusion, it was found that the ratio of Bcl-2/Bax significantly decreased from 1.43 to 0.65 and the relative expression of GADD45 α was 5.21 times higher (Figure 3). Treatment with a high

dose of CPCGI reversed the effect of MCAO on Bcl-2/Bax ratio and GADD45 α induction, suggesting CPCGI possesses antiapoptotic properties within the context of MCAO reperfusion injury.

CPCGI improves synaptic function in the ischemic cortex

Functional synaptic activity is generally required to maintain the normal physiological functions of neurons. Because GM-1 can act as a neurotrophic factor in the central nervous system by modulating axon stability,¹² the effect of CPCGI administration on synaptic function post-MCAO reperfusion was investigated. In the ischemic cortex, the expression levels of Synaptophysin, a protein necessary for the proper structure and function of synapses,³² were found to be markedly downregulated by ischemia-reperfusion injury 14 days post-MCAO, and this effect was partially reversed by treatment with CPCGI although not to a significant extent (Figure 4A and B).

Functional synaptic activity requires sufficient energy and proper synaptic protein expression. The expression levels of KIFC2, SNARE complex, and Complexin-1/2 were measured, which involved in the modulation of mitochondria retrograde axonal transport and the neurotransmitter release.^{33–35} It was found that KIFC2 protein levels in the ischemic cortex of MCAO-treated rats were significantly

lower compared with the sham group (Figure 4A and F). Furthermore, MCAO also decreased the protein levels of SNAP25 and Complexin-1/2 (Figure 4A, C, and E). While CPCGI treatment partially reversed, these pathological changes and all above proteins showed a certain level of recovery. In addition, MCAO reperfusion had no effect on the expression levels of Syntaxin (Figure 4A and D).

Figure 3 CPCGI inhibits apoptosis induced by MCAO in the ischemic cortex.

CPCGI induces upregulation of UCP3 in the ischemic cortex after MCAO reperfusion

During ischemic stroke, GM-1 and carnosine exert their neuroprotective effects by inhibiting macromolecular

oxidation.^{36,37} UCP3 is an uncoupling protein (UCP) family member and regulates mitochondrial adenosine-triphosphate (ATP) and reactive oxygen species (ROS) production.³⁸ It has been shown that fluctuations in UCP3 expression mediate oxidative stress induced by ischemia–reperfusion.³⁹

Figure 5 CPCGI increases the expression of UCP3 post-MCAO in the ischemic cortex.

Notes: The intensity of each band was normalized to β -actin. Data are expressed as mean $\pm$ SD. * $P < 0.05$ versus Sham; # $P < 0.05$ versus Model; $n = 3$.

Abbreviations: CPCGI, compound porcine cerebroside and ganglioside injection; MCAO, middle cerebral artery occlusion; SD, standard deviation; H, high dose; L, low dose.

In our study, 14 days after MCAO reperfusion, UCP3 protein levels were ~ 4.95 times lower in the model group compared with the sham group, and treatment with a high dosage of CPCGI partially reversed this effect (Figure 5).

Discussion

This study aimed to assess the protective effects of CPCGI post-cerebral ischemia–reperfusion injury in vivo. It was found that CPCGI reduced infarct size, improved neurological function, and accelerated the recovery of somatosensory function 14 days after MCAO reperfusion, as the positive control Gintonin did. Gintonin, so-called *Ginkgo biloba* extract (EGB), has been used in traditional medicines for centuries, and abundant evidences show that treatment with EGB has a significant protective effect on experimental animal models of stroke.²⁵ Rats treated with a high dosage of CPCGI also showed an increase of NeuN-positive cells in ischemic cortex penumbra post-reperfusion. These results support the ability of CPCGI to protect against neurological damage caused by ischemia–reperfusion injury.

In a previous study, it was found that CPCGI protected against cerebral ischemia–reperfusion injury in rats via the activation of mitophagy,²⁴ a process that maintains mitochondrial homeostasis by selectively removing

damaged mitochondria. Accumulation of damaged mitochondria can result in the release of proapoptotic proteins (eg, cytochrome c) from the mitochondrial matrix into the cytoplasm, activating the intrinsic pathway of apoptosis and, eventually, inducing neuronal cell death. The present study further characterized the expression of apoptotic proteins (Bcl-2, Bax, and GADD45 α) in the ischemic cortex using Western blot analysis. The ratio of Bcl-2/Bax, an important marker of intrinsic apoptosis,⁴⁰ was significantly decreased by ischemia–reperfusion injury, and this effect was reversed by CPCGI treatment, suggesting that CPCGI inhibits apoptosis in the brain. CPCGI also suppressed the expression of GADD45 α , a protein that has been shown to activate apoptosis by inducing the translocation of BCL2L11/Bim from the cytoskeleton to the mitochondria.⁴¹ Interestingly, GADD45 α has also been shown to inhibit autophagy by directly interacting with Beclin1,⁴² suggesting that CPCGI might induce autophagy as a protective mechanism in the ischemic cortex. The results were in accordance with our previous data.

Most critical functions carried out by the nervous system require proper synaptic activity, including the release of neurotransmitters from presynaptic terminals to promote efficient communication between neurons. Some core proteins are involved in a complicated machinery that modulate the exquisite regulation of the release in varied presynaptic plasticity processes, underlying diverse forms of information processing in the brain.⁴³ SNAREs and Complexins, through a series of complex interactions, facilitate neurotransmitter release by mediating the fusion of synaptic vesicles with the plasma membrane.⁴⁴ Fourteen days post-MCAO reperfusion injury, a significant decrease in the expression of Complexin-1/2 and SNAP25 was observed. However, protein levels of Syntaxin (also a SNARE component) were unchanged. These data indicate that treatment with a high dosage of CPCGI prevented the MCAO-mediated downregulation of Complexin-1/2 and SNAP25. Moreover, CPCGI partially inhibited the effect of MCAO reperfusion on the expression levels of Synaptophysin, indicating the recovery of synaptic activity.

Proper synaptic activity requires a sufficient amount of ATP production from mitochondria that are transported away from the cell body to the location of the synapse. Therefore, the expression levels of KIFC2 in the ischemic cortex were assessed, which plays a crucial role in mitochondrial retrograde axonal transport. Remarkably, it was found that CPCGI attenuated the downregulation of KIFC2 induced by ischemia–reperfusion. Furthermore, CPCGI increased the expression of UCP3, a known regulator of mitochondrial ATP and ROS production,³⁸ post-MCAO in the ischemic

cortex. These data suggest that mitochondrial homeostasis is maintained in response to treatment with CPCGI, even after ischemia–reperfusion.

Conclusion

In summary, this study confirms the neuroprotective effect of CPCGI in rats after MCAO reperfusion injury and validates its clinical potential as a potent treatment for ischemic stroke. It proposes that CPCGI acts as a multitarget drug, inhibiting apoptosis, improving synaptic function, and reducing mitochondrial dysfunction. However, because the observations are limited to an MCAO model of ischemia–reperfusion, additional investigation is required to characterize the nature of the protective effects of CPCGI.

Neuropsychiatric Disease and Treatment

Dovepress

Publish your work in this journal

Neuropsychiatric Disease and Treatment is an international, peer-reviewed journal of clinical therapeutics and pharmacology focusing on concise rapid reporting of clinical or pre-clinical studies on a range of neuropsychiatric and neurological disorders. This journal is indexed on PubMed Central, the 'PsycINFO' database and CAS,

Submit your manuscript here: <http://www.dovepress.com/neuropsychiatric-disease-and-treatment-journal>

and is the official journal of The International Neuropsychiatric Association (INA). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
