Superficial carbon dioxide fractionation improves the antioxidative activity, anti-inflammatory activity, and therapeutic index of Panax ginseng

Abstract: Superficial carbon dioxide (SC-CO₂) fractionation technology can effectively separate different types of ginsenosides from the roots of Panax ginseng, which have been shown to possess various physiological activities. The objective of this study was to evaluate the antioxidative and anti-inflammatory activities as well as the therapeutic index of SC-CO₂ fractions from P. ginseng C.A. Meyer. Of the various extracted fractions and residues, the F3 fraction exhibited the highest antioxidative property. The half maximal effective concentration (EC₅₀) values of the F3 fraction for reducing power, hydrogen peroxide scavenging activity, and thiobarbituric acid assay were 4.51, 2.60, and 0.22 mg/mL, respectively. The F3 fraction also possessed the strongest anti-inflammatory effect in lipopolysaccharide-stimulated human THP-1 monocyte-like cell line, by decreasing tumor necrosis factor alpha (TNF-α) and interleukin 6 (IL-6) production. In addition, the F3 fraction exhibited a high therapeutic index, which is the ratio of 50% cytotoxic concentration (CC₅₀) and EC₅₀. In conclusion, high antioxidative and anti-inflammatory activities and therapeutic index value were observed in the F3 fraction of the roots of P. ginseng C.A. Meyer. SC-CO₂ technology is a feasible method to improve the antioxidative and anti-inflammatory activities of Panax ginseng.

Keywords: anti-inflammation, antioxidative activity, Panax ginseng, superficial carbon dioxide fractionation

Introduction

The root of Panax ginseng is a widely used traditional Asian medicine due to the scientific claims of its antioxidative, cardiovascular protective, immune regulatory, antidiabetic, and anticarcinogenic properties. The major pharmacological ingredients of ginseng are triterpene saponins called ginsenosides, which are a family of triterpenoids (17 carbons in a four-ring structure) with various sugar moieties attached to the C-3 and C-20 positions. Based on the type, quantity, and the position of the sugar attachment, ginsenosides are categorized into three types: protopanaxadiol (PPD)-type ginsenosides, protopanaxatriol (PPT)-type ginsenosides, and oleanolic acid-type saponins. Deglycosylated ginsenosides are included in PPD- or PPT-type ginsenosides. Previous studies showed that ginsenoside types could affect its pharmacological activities. For example, compared to PPD or PPT, deglycosylated ginsenosides Rh₁, Rh₂, Rg₁, and K exhibited a higher anticancer activity and immune regulation. In addition, deglycosylated ginsenosides Rg₃, Rk₁, and Rg₅ also possess a stronger antioxidant capacity than that of PPD or PPT.

Supercritical carbon dioxide (SC-CO₂) extractive fractionation is a separation technology based on the solubility of active compounds, which in turn depends on
vapor pressure and polarity. In our previous study, the ethanolic extract (E) of *P. ginseng* was SC-CO$_2$ fractionated in series separators under varying pressures to yield a residue (R) (material insoluble in SC-CO$_2$) and three extracted fractions (fractions F1, F2, and F3). Among those fractions, E possessed the highest content of total ginsenosides and F3 had the highest content of deglycosylated ginsenosides.$^{17}$ The aim of this study was to further clarify the antioxidative and anti-inflammatory activities of SC-CO$_2$-fractionated *P. ginseng*.

**Materials and methods**

**Chemicals**

*P. ginseng* C.A. Meyer root powder was purchased from Wah Hong Ginseng Company, Kaohsiung, Taiwan. 1,1-Diphenyl-2-picrylhydrazyl (DPPH), trichloroacetic acid (TCA), ferrocyanide, phenol, hydrogen peroxide (H$_2$O$_2$), 4-aminoantipyrine, lipopolysaccharides (LPS), phorbol 12-myristate 13-acetate (PMA), and horseradish peroxidase (HRP) were purchased from Sigma Chemical Co. (St Louis, MO, USA). Sulfuric acid and sodium chloride were purchased from J. T. Baker (Phillipsburg, NJ, USA). THP-1 human monocytic cells were obtained from the American Type Culture Collection TIB-202. Roswell Park Memorial Institute (RPMI) 1640 medium, fetal bovine serum (FBS), penicillin, and streptomycin were purchased from Gibco BRL (Grand Island, NY, USA). Thiobarbituric acid-reactive substance (TBARS) Assay Kit 10009055 was obtained from Cayman Chemical (Ann Arbor, MI, USA). OptEIA ELISA kits specific against human cytokines, tumor necrosis factor alpha (TNF-α), and interleukin 6 (IL-6) were obtained from BD Bioscience (San Diego, CA, USA).

**Extraction and fractionation**

The fractionation of *P. ginseng* was prepared according to methods described in our previous work.$^{17}$ Ethanolic extracts of *P. ginseng* C.A. Meyer root powder were fractionated using SC-CO$_2$ at a temperature of 45°C, pressure of 30 MPa, flow rate of CO$_2$ at 4 mL/min, and an inflow rate of sample at 1 mL/min. Four separators connected in series at pressures of 30, 25, 20, and 15 MPa were used to yield F1, F2, F3, and R, respectively. The collected samples were then freeze-dried and stored at −20°C until use.

**Antioxidant activity assays**

The antioxidant properties investigated were expressed as half maximal effective concentration (EC$_{50}$) values for comparison. EC$_{50}$ values were calculated by interpolation from linear regression analysis, which denoted the concentration of the sample required to decrease the absorbance by 50%. Higher EC$_{50}$ values indicate lower effectiveness in antioxidative properties.

**Determination of DPPH radical scavenging ability**

The scavenging ability of DPPH radicals was assayed according to the method by Shimada et al$^{18}$ with modifications. Each extract or fraction (1–20 mg/mL) in deionized water (4 mL) was mixed with 1 mL ethanolic solution of DPPH, resulting in a final concentration of 0.5 mM DPPH. The mixture was vigorously shaken and left to stand for 30 min in the dark. DPPH radical reduction was determined by measuring the absorbance (A) at 517 nm. The DPPH scavenging activity (%) was calculated as follows: scavenging ability (%) = [1 − (A$_{sample}$/A$_{control}$)] × 100.

**Determination of reducing power**

The reducing power of the extract or fractions was determined using the method described previously.$^{19}$ A series of the samples (0.1–20 mg/mL) were diluted in 0.2 M phosphate buffer (pH 6.6) containing 1% ferrocyanide. After the mixture was incubated at 50°C for 20 min, 10% TCA (2.5 mL) was added to a portion of this mixture (5 mL) and centrifuged at 3,000×g for 10 min. The supernatant was mixed with distilled water (2.5 mL) containing 1% ferric chloride (0.5 mL), after which the absorbance was measured at 700 nm.

**Determination of H$_2$O$_2$ scavenging ability**

The H$_2$O$_2$ scavenging activity of each fraction was assayed according to the method described by Yen and Chung$^{20}$ with slight modification. Different concentrations of sample (1 mL) were mixed with 400 µL of H$_2$O$_2$ solution (4 mM) and then incubated at room temperature for 20 min. The mixture was supplemented with 600 µL of HRPase-phenol red solution. After 10 min, the absorbance (A) was measured at 610 nm with a spectrophotometer. Distilled water was used as a control, and ascorbic acid was used for comparison. The H$_2$O$_2$ scavenging activity (%) was calculated as follows: scavenging activity (%) = [1 − (A$_{sample}$/A$_{control}$)] × 100.

**Determination of lipid oxidation**

The analysis of malondialdehyde (MDA) by thiobarbituric acid (TBA) assay was based on the reaction of MDA with TBA, forming a MDA–TBA2 adduct that absorbs strongly at 532 nm. The assay was conducted according to the manufacturer’s instructions (TBARS Assay Kit Item No 10009055).
Briefly, serial dilutions of MDA standard (0, 0.0625, 0.125, 0.25, 0.5, 1, 2.5, and 5 μM) or test samples were added to 100 μL of sodium dodecyl sulfate solution and mixed well, followed by adding another 4 mL of color reagent. The reactions were preceded at boiling temperature at 90°C for 1 h to form the MDA–TBA adduct. The reactions were stopped by placing the reaction mixture into an ice bath for 10 min, followed by centrifugation at 1,600×g at 4°C for 10 min. The reactions were then warmed and stabilized at room temperature for 30 min followed by measuring colorimetrically at 530–540 nm. The equation of the average absorbance used for each standard and sample was as follows: MDA (μM) = [(corrected absorbance) – (y-intercept)/slope].

### Anti-inflammatory assay

#### Cell viability

Human THP-1 cells were treated with different concentrations of E, R, F1, F2, or F3 (100–800 μg/mL) for 24 h, and cytotoxicity against the THP-1 cells was assessed via trypan blue exclusion counting assay. \( CC_{50} \) was defined as the concentration of compound (μg/mL) required for a 50% reduction in cell viability.

#### LPS-mediated inflammation in THP-1 cells

THP-1 human monocytic cells were maintained in suspension in high-glucose RPMI 1640 medium containing 10% FBS, L-glutamine (2 mM), penicillin (100 U/mL), and streptomycin (100 μg/mL). To induce differentiation, the cells in 12-well culture dishes at a density of 2×10^5 cells/mL were cultured with RPMI medium containing 10 μM PMA for 48 h. After induction, differentiated cells adhered to the flask, whereas undifferentiated monocytic cells remained in suspension and were removed by washing with PBS. To examine anti-inflammatory capacities of the ginseng E, R, F1, F2, or F3, differentiated THP-1 cells cultured in serum-free RPMI were pretreated with ginseng samples (13–400 μg/mL) for 1 h, and then stimulated with LPS (0.1 ng/mL) for 24 h.

### Cytokine assays

After stimulation with LPS, the cytokine concentrations of cell supernatants were determined using OptEIA ELISA kits specific against human cytokines, TNF-α, and IL-6, according to the manufacturer’s instructions.

### Statistical analysis

Data were expressed as mean ± standard deviation (SD) of three replicates. Statistical evaluation of data was performed by Pearson’s product-moment correlation analysis and one-way analysis of variance, followed by Duncan post hoc tests. A \( P \)-value of <0.05 was considered statistically significant.

### Results and discussion

Ginsenosides are one of the main active ingredients of *P. ginseng* and are thought to be responsible for the various therapeutic effects of ginseng.\(^\text{12}^\) Our previous study demonstrated that SC-CO\(_2\) fractionation technology could successfully fractionate ginseng extracts into R, F1, F2, and F3 fractions, which were found to be associated with different levels of biological activities due to varying contents of ginsenoside types.\(^\text{17}^\) The content of total ginsenosides was highest in E, while the content of deglycosylated ginsenosides was highest in F3. Findings from this study demonstrated that SC-CO\(_2\) fractionation technology could significantly increase the antioxidative activities, including H\(_2\)O\(_2\) scavenging, reducing power, and antilipid oxidation of the fractions compared to the original *P. ginseng* extract (Table 1). A dose-dependent relationship was observed between the antioxidative activities tested and the concentrations of the extract and fractions. Similar to the observation made by Chien et al,\(^\text{17}^\) our study showed that the DPPH scavenging ability, in a decreasing order, was \( R > F1 > E > F2 > F3 \). On the other hand, F3 exerted the strongest activities in the other three antioxidative assays (H\(_2\)O\(_2\) scavenging, reducing power, and antilipid oxidation). The inconsistencies

regarding the outcomes among various antioxidative assays might be attributed to different reaction mechanisms of the assays and the structural features of the antioxidant.21 Active constituents of various *P. ginseng* fractions appeared to exert different aspects of protective effects against harmful reactive oxygen species and will require further investigation to fully elucidate.

Previous research reported that ginsenosides exhibited a strong antioxidant capacity.22 In particular, studies found that deglycosylated ginsenosides Rg₃, Rk₁, and Rg₅ possessed a stronger antioxidative capacity than PPD or PPT.23 Table 2 lists the correlation coefficients between ginsenoside types and their antioxidative activities. F3, the fraction that deglycosylated ginsenosides are primarily present, was the fraction with the strongest capacity for protecting oxidative damage. Deglycosylated ginsenosides (including Rh₁, Rh₂, and Rg₃) might be the main ingredient responsible for the high antioxidative capacity in *P. ginseng* C.A. Meyer.

Ginseng has also been recognized as an immune modulator to regulate the generation of proinflammatory cytokines. Ginsenosides, especially deglycosylated ginsenosides, are considered to be the key immune adjuvanticity molecules among the whole ginseng extract.6,14,24 Since SC-CO₂ fractionation altered the distribution of ginsenoside types in fractions, the cytotoxic and anti-inflammatory effects of ginseng SC-CO₂ fractions in human THP-1 monocytes were further examined. As depicted in Figure 1, the concentration of a 50% reduction in cell viability of the SC-CO₂-fractionated samples, in a decreasing order, was R (796 µg/mL), E (326.8 µg/mL), F2 (743 µg/mL), F1 (704 µg/mL), and F3 (292 µg/mL). F3 exhibited the highest cytotoxicity to THP-1 cells compared to other fractions.

Next, the anti-inflammatory ability of the SC-CO₂-fractionated samples was evaluated in LPS-stimulated THP-1 cells. The dose-dependent inhibitions against LPS on the production of proinflammatory cytokines, TNF-α, and IL-6

Antioxidative and anti-inflammatory activities of *Panax ginseng*

in THP-1 cells are shown in Figures 2 and 3, respectively. F3 was the fraction with the highest capacity to protect THP-1 cells against both the increasing TNF-α and IL-6 induced by LPS. Table 3 shows that the concentration of SC-CO₂-fractionated samples of *P. ginseng* C.A. Meyer to achieve a half reduction of TNF-α (EC₅₀) by LPS in THP-1 cells, in a decreasing order, was F2 (364 µg/mL), R (327 µg/mL), F1 (304 µg/mL), E (281 µg/mL), and F3 (22 µg/mL). It should be noted that F3 showed not only the lowest EC₅₀ value, but the magnitude was also less than one-tenth of the other fractions. In addition, F3 also showed the lowest EC₅₀ value for reducing IL-6 production. The EC₅₀ of the different SC-CO₂-fractionated samples for IL-6 was determined as, in a decreasing order, R (220 µg/mL), F2 (212 µg/mL), E (190 µg/mL), F1 (188 µg/mL), and F3 (47 µg/mL). Again, it should be noted that F3 showed not only the lowest EC₅₀ value, but the magnitude was also at least 75% less than the other fractions. It has been reported that some ginsenosides,
such as Rb1 and Rg1, could significantly inhibit TNF-α production.25 Rb1, Rb2, Rd, and the metabolite compound K (CK) have been shown to potentiate the responses of P2X7, a molecule that has achieved the status of an essential immunomodulatory receptor.26 Furthermore, Rg3 has been shown to be a potential adjuvant in OVA-immunized BALB/c mice.27 In this study, we showed that F3, the deglycosylated ginsenoside-enriched fraction fractionated by SC-CO2, composed of Rh1, Rh2, and Rg3, exhibited the highest anti-inflammatory activity in THP-1 cells compared to the other tested fractions.

Furthermore, a therapeutic index (CC50/EC50) was calculated to evaluate the safety window of each extract in THP-1 cells for anti-inflammatory effect on TNF-α and IL-6 production. As indicated in Table 3, F3 exhibited the highest therapeutic index value for both TNF-α (13.1) and IL-6 (6.2) among the tested extracts of P. ginseng, suggesting a potential for further evaluation of its pharmacological applications.

### Conclusion

Fractionation using SC-CO2 could significantly increase the deglycosylated ginsenoside content and antioxidative activities in vitro. This study was also the first to demonstrate that SC-CO2-fractionated F3 exhibited a high therapeutic index in regulating the functionality of immune cells. Therefore, findings from this study suggested a novel application of SC-CO2 to obtain a deglycosylated ginsenoside-enriched fraction from the roots of P. ginseng C.A. Meyer with strong antioxidative and anti-inflammatory activities.
