Abstract: Methicillin-resistant Staphylococcus aureus (MRSA) is an important nosocomial and community pathogen. The objectives of this study were to estimate the prevalence of multidrug-resistant MRSA strains in clinical specimens and to investigate the sensitivity pattern of these strains against various antibiotics used for treating hospitalized and out patients. Strains were identified using standard procedures, and their sensitivity pattern was investigated using such techniques as disc diffusion, minimum inhibitory concentration (MIC), and the mecA gene PCR. Among 783 isolates of S. aureus, 301 (38.44%) were methicillin-resistant, of which 217 (72.1%) were found to be multidrug-resistant. Almost all MRSA strains were resistant to penicillin, 95.68% were resistant to cotrimoxazole, 92.36% were resistant to chloramphenicol, 90.7% were resistant to norfloxacin, 76.1% were resistant to tetracycline, and 75.75% were resistant to ciprofloxacin. Vancomycin was the most effective drug, with only 0.33% of MRSA strains being resistant to it. It is concluded that antibiotics other than vancomycin can be used as anti-MRSA agents after a sensitivity test so as to preclude the emergence of resistance to it and that prevailing problems in chemotherapy will escalate unless indiscriminate and irrational usage of antibiotics is checked.

Keywords: multidrug-resistant MRSA, prevalence, India

Introduction

Infections caused by Staphylococcus aureus have a poorer prognosis when the infecting strain is MRSA (Cosgrove et al 2003). Since its first report in 1961 (Jevons 1961), the strain has been progressively causing increased mortality, morbidity, and health care costs with skin and soft tissue infections, ventilator-associated pneumonia, catheter associated bacteremia, and many other infections in hospitals and communities. First detected in hospitals, methicillin resistance is now increasingly recognized in the community (Chambers 2001).

In addition to dire consequences of infections, MRSA strains are important for their resistance to many other commonly used antibiotics and the emergence of resistance to vancomycin, the drug that has been used to treat MRSA infections for more than three decades. Thus, it is immensely important to study the antibiogram of MRSA in a given hospital so that the results of such studies can be exploited to minimize the irrational use of vancomycin when other antibiotics would cure an infection. Reports of emergence of vancomycin resistance in S. aureus from India (Assadullah et al 2003; Tiwari and Sen 2006; Saha et al 2008) further justify this necessity.

The prevalence of MRSA has varied from hospital to hospital in various countries. About 40% of S. aureus infections acquired in large US hospitals (500 or more beds) are methicillin-resistant (Red Book 2003). Prevalence is constantly soaring in many countries, and in some hospitals, more than half of all S. aureus disease isolates are MRSA (Voss and Doebbeling 1995). In many American and European hospitals, the percentage of MRSA has ranged from 29% to 35% of all clinical isolates. Meanwhile,
information from developing countries is provided only by relatively sophisticated hospitals (Degerli et al. 2000; Gastmeier et al. 2000; Santos et al. 2000); as a consequence, the data on MRSA prevalence, most of which are from developed countries, are inadequate in estimating the overall global distribution (Pulimood et al. 1996; Verma et al. 2000; Majumder et al. 2001; Tahnkiwale et al. 2002; Anupurba et al. 2003; Mohanty et al. 2004; Rajadurairapandi et al. 2006; Mehta et al. 2007; Mull et al. 2007).

The present study uncovers the prevalence of multidrug-resistant MRSA strains and investigates their antibiotic sensitivity pattern in a tertiary care hospital of northern India.

**Material and methods**

During August 2002 and June 2006, a total of 783 strains of *S. aureus* were isolated from various specimens of different patients visiting and admitted at Sir Sundar Lal Hospital, a 972 bed tertiary care teaching hospital of Banaras Hindu University at Varanasi, India.

**Isolation and identification of staphylococci from clinical specimens**

All specimens, except urine for which cystine lactose electrolyte deficient agar (HiMedia, New Delhi, India) was used, were cultured on blood agar and MacConkey agar (HiMedia, New Delhi, India). *S. aureus* was identified and differentiated from related organisms on the basis of colony morphology, Gram staining, catalase test, tube coagulase test using rabbit plasma, slidex staph plus (Biomerurix India Ltd, New Delhi, India), thermonuclease and acetoin production, and mannitol fermentation (Barid 1996). Using growth on blood agar, all the strains were subjected to the following tests. *S. aureus* ATCC 25923 (meCA negative) and ATCC 43300 (meCA positive) were used for the quality control of all the tests.

**Disc diffusion test by Kirby–Bauer method**

Mueller–Hinton agar (MHA) plates were overlaid with the saline suspension of a strain (turbidity matching 0.5 McFarland standard), and the following antibiotic discs procured from HiMedia, India were placed on the plate after 10 minutes, with six discs on a plate: penicillin (10 μg), oxacillin (1 μg), gentamicin (10 μg), tobramycin (30 μg), amikacin (30 μg), netilmicin (30 μg), norfloxacin (10 μg), ciprofloxacin (5 μg), chloramphenicol (30 μg), erythromycin (15 μg), tetracycline (15 μg), trimethoprim/sulfamethoxazole (1.25/23.75 μg), nitrofurantoin (300 μg), vancomycin (30 μg), and sulbactam/cefoperazone (30/75 μg). After 24 and 48 h of incubation at 35 °C, the plates were read using the NCCLS break-points as reference (NCCLS 2004).

**Oxacillin MIC test**

Gradient plates of MHA containing 2% NaCl were prepared with doubling dilutions (from 0.25 μg/ml to 256 μg/ml) of oxacillin. Inoculum was prepared by diluting 0.5 McFarland equivalent suspension of a strain with sterile normal saline to the concentration of 10⁴ CFU/ml. The plates were spot-inoculated and incubated at 35 °C for 24 h. An oxacillin minimum inhibitory concentration (MIC) of ≤2 μg/ml indicated that the strain was susceptible and that of >2 μg/ml resistant (NCCLS 2003).

**The meCA gene detection by PCR**

Staphylococcal DNA was isolated using chloroform: phenol extraction method (Sambrook et al. 1989). The primers used for detection of the meCA gene were MecA1 (5′-GTA GAA ATG ACT GAA CGT CCG ATA A) and MecA2 (5′-CCA ATT CCA CAT TGT TTC GGT CTA A), as described earlier (Geha et al. 1994). A Biometra DNA thermocycler was programmed for initial denaturation at 94 °C for 4 min; 30 cycles of amplification (denaturation at 94 °C for 45 sec, annealing at 56 °C for 45 sec, and extension at 72 °C for 30 sec); and a final extension at 72 °C for 2 min. To visualize, 10 μl of the PCR amplicon was loaded in 2% agarose gel in TBE (0.089 M Tris, 0.089 M boric acid, 0.002 M EDTA) containing 0.5 μl/ml of ethidium bromide and visualized by using UV transillumination at 300 nm. DNA fragments of 310 bp corresponded to the meCA gene.

**Results**

Of the 783 *S. aureus* strains (503 from outpatient departments [OPDs] and 280 from wards), 301 (38.44%) – 187 from OPDs and 114 from wards – showed methicillin resistance in disc diffusion and MIC tests and were confirmed as MRSA by the meCA gene PCR. The remaining 482 (61.56%) were MSSA. Table 1 shows the pattern of resistance shown by MRSA strains as well as compares its distribution in OPDs and wards. Resistance to penicillin was highest (97%) followed by cotrimoxazole (95.68%), chloramphenicol (92.36%), and norfloxacin (90.7%).

The resistance pattern of MRSA was somewhat varying between OPDs and wards for macrolides, chloramphenicol, tetracycline, cotrimoxazole, nitrofurantoin and betalactam/betalactamase inhibitor combination; the pattern was more or less same for other antibiotics (Table 1).

Out of 301 MRSA isolates, 217 (72.1%) were multidrug resistant, with 136 being resistant to more than three
High prevalence of MRSA in India

Antimicrobials except vancomycin. One MRSA strain was found to be resistant to all antibiotics including vancomycin (Table 2).

Frequency of isolating MRSA was maximum in cutaneous and wound specimens (42.2%) followed by blood, respiratory specimens, and urine (Table 3).

Discussion

Studies show that the epidemiology of MRSA over different parts of India is not uniform. The present study reports 38.44% MRSA among S. aureus isolates, whereas an earlier study done in the same hospital here had shown a higher prevalence of 54.8% (Anupurba et al 2003). Some studies have reported comparable prevalence: 38.56% in Delhi (Mohanty et al 2004), 31.1% in a multicenter study in Tamilnadu (Rajaduraipandi et al 2006), and 39.50% in South Gujarat (Mulla et al 2007). In contrast, other studies have reported entirely different prevalence: 24% in Vellore (Pulimood et al 1996), 80.89% in Indore (Verma et al 2000), 52.9% in Assam (Assadullah et al 2003), 19.56% in Nagpur (Tahnkiwale et al 2002), and 24% in Chandigarh (Mehta et al 2007). Although it’s extremely difficult to explain these conflicting data with regards to both time and place of study, the variation is probably due to differential clonal expansion and drug pressure in community.

Given the fact that staphylococci spread by direct or indirect person-to-person contact, the emergence of multidrug-resistant stains of MRSA is worrisome in the present therapeutic scenario. Multidrug resistance was defined as resistance of a MRSA strain towards three or more antibiotics at a given point of time. In the USA, some workers (Styers et al 2006) have reported multi-drug resistance rates of 67.8% (for inpatients) and 65% (for outpatients) in lower respiratory tract MRSA isolates. In Nigerian women, a total of 43 S. aureus out of 60 were found to be multidrug resistant (Onanuga et al 2005). We found a high percentage of multidrug-resistant MRSA (72.1%) in our hospital. If we look into the Indian literature, it seems the burden of multi-drug-resistant-MRSA is increasing over time: for instance, 23.2% was reported by Majumder and colleagues in 2001; 32% by Anupurva and colleagues in 2003; and 63.6% by Rajaduraipandi and colleagues 2006. The lesson is clear: MRSA surveillance and strict drug policy are of paramount importance, or else the threat will increase.

**Note:** *MRSA strains which were resistant to three or more than three antibiotics tested were considered to be multidrug-resistant MRSA.

**Abbreviation:** MRSA, methicillin-resistant Staphylococcus aureus.
The MRSA strain that showed resistance to all antimicrobials including vancomycin was isolated from a 56-year-old male patient admitted in post-operative ward of our hospital. The zone of inhibition shown by this strain in response to vancomycin disc was less than 9 mm; therefore we tentatively characterized this strain as vancomycin resistant \textit{S. aureus}. Molecular investigation of the strain for the presence of \textit{vanA/B} gene is needed to clarify its exact status.

Patterns of resistance shown by MRSA to Beta-lactams, aminoglycosides and quinolones are more or less identical in OPDs and wards, while the same to erythromycin, chloramphenicol, tetracycline, cotrimoxazole, nitrofurantoin, and beta-lactam/beta-lactamase inhibitor combination present certain level of difference between their distributions in OPDs and wards. This is a reflection of differential drug pressure.

Currently, the majority (80%–90%) of \textit{S. aureus} strains in communities are beta-lactamase producers hence resistant to penicillin and ampicillin (Paradisi et al 2001; Ang 2004). Recently more than 90% isolates from South Maharashrra have been found resistant to ampicillin, tobramycin, penicillin, erythromycin, kanamycin and gentamicin, whereas only 39.1% of strains are resistant to methicillin (Kandle et al 2003). The choice is obviously oxacillin; however, fearing MRSA, clinicians may exploit vancomycin. Our study reports that antibiotics other than vancomycin – for instance, amikacin, tobramycin, gentamicin, cefoperazone/sulbactam – can be promising if a susceptibility testing is done, reserving vancomycin for life-threatening infections. A retrospective study of bacterial isolates from cases of neonatal septicemia over a period of five years from Chandigarh, India, has also reported that netilmicin was the most effective drug for \textit{S. aureus} (Agnihotri et al 2004).

Factors contributing to drug resistance in developing countries are myriad. Antibiotics are available without prescription at drug stores or even at general stores and injudiciously used in communities, animal husbandries, and fisheries. Traditional practitioners use allopathic drugs, and many practitioners who earn by selling medicines prescribe more drugs than necessary (Holloway 2000). In a study from five districts of Tamilnadu, India, 285 general practitioners and specialists believed that antibiotics are overprescribed: purulent discharge (65%), antibiotic-resistance concerns (48%), fever (40%), and patient satisfaction (29%) being the strong reasons for overprescription (Sivagnanan et al 2004). Poor quality antibiotics are produced at local levels, and patients show poor compliance to costly antimicrobials (Hart 1998). Therefore, there is no other way than to foil these malpractices, to constantly conduct microbiological surveillance like this, and follow infection control measures like hand washing and other aseptic techniques if we are to avoid therapeutic crisis resulting from multidrug-resistant MRSA.
