Clinical relevance of lysyl oxidase-like 2 and functional mechanisms in glioma

Introduction: Glioma is the most frequent malignancy of the adult central nervous system with high recurrence risk and poor prognosis. Understanding the biological molecular mechanisms involved in glioma progression is critical for studying oncogenic mechanisms and improving prognosis. Lysyl oxidase-like 2 (LOXL2) is a kind of lysyl oxidase catalyzing the formation of peptidyl-lysine residues and promoting intramolecular cross-linking, especially for proteins in extracellular matrix. Our study explored the expression pattern of LOXL2 in glioma for the first time and found that its high expression was associated with larger tumor size and advanced tumor grade ($P<0.05$). Moreover, univariate and multivariate analyses revealed LOXL2 as a novel independent prognostic factor for the overall survival of glioma patients.

Methods: To evaluate the detailed functional roles of LOXL2, we tested its oncobiology characteristics in U87-MG cells with overexpression and knockdown experiments.

Results: Cellular results demonstrated that LOXL2 overexpression enhanced cell proliferation and invasion, while LOXL2-siRNA attenuated cell viability. Furthermore, our data identified the participation of E-cadherin, Snail1, Src, and FAK proteins downstream of LOXL2. Notably, by using immunoprecipitation and mass spectrometry strategies, we initially verified the interaction between LOXL2 and HDAC2, indicating the existence of a protein complex containing LOXL2/Snail1/HDAC2. Additionally, the expression of HDAC2 protein was highly correlated with that of LOXL2 in clinical glioma tissues ($P=0.02$), further implying the synergic oncogenic roles of these 2 proteins.

Conclusion: LOXL2 is a promising prognostic biomarker and may be further evaluated as a potential drug target for patients with glioma.

Keywords: glioma, HDAC2, invasion, LOXL2, prognosis

Introduction

Glioma is the most frequent primary brain malignancy of adults and is characterized by quick progression and poor survival.\(^1\)\(^2\) According to the World Health Organization (WHO), glioma can be classified into pilocytic astrocytoma (grade I), diffuse astrocytoma (grade II), anaplastic astrocytoma (grade III), and glioblastoma (grade IV).\(^3\) Surgical resection is the most effective treatment for glioma; meanwhile, radiotherapy and chemotherapy development have led to significant progress. However, the clinical outcomes of glioma patients are far from satisfactory, with more than half of the patients dying within 2 years after diagnosis due to, inevitably, postoperative recurrence.\(^4\) One of the major prognostic factors is the tumor grade, and it is widely used in clinical prognosis. Accumulating studies have shown that even patients suffering from the same tumor type and at the same tumor grade may have completely different prognosis.\(^5\) Therefore, an understanding of the biological and molecular factors involved in the progression of glioma is critical for further improvement in prognosis prediction and therapy selection.\(^6\)
Recent evidence revealed that the extracellular matrix (ECM) plays critical roles in modulating tumor growth and metastasis. The biological change in ECM can directly regulate cell adhesion and dissemination, and thus more attention is focused on studying the role of ECM-related proteins in tumor progression. For example, the lysyl oxidase (LOX)-like 2 (LOXL2), a member of the LOX family, is a kind of secreted, copper-dependent amine oxidase. LOXL2 contains a copper-binding motif and a lysyl-tyrosyl-quinone group in its C-terminus, and thus it can oxidatively deaminate the peptidyl-lysine residues and generate reactive aldehyde groups to initiate covalent inter- and intramolecular cross-linking.

The ECM protein collagen and elastin are well-known substrates of LOXL2. Additionally, it has been reported that E-cadherin was downregulated by LOXL2, resulting in enhanced epithelial–mesenchymal transition process. Although, the above studies implied the possible involvement of LOXL2 in tumor progression, its expression pattern and clinical significance in glioma have not been illuminated.

Here in this study, we explored the expression and prognostic role of LOXL2 in glioma patients for the first time. Besides, we characterized the role of LOXL2 in promoting glioma cell proliferation and invasion using U87-MG glioma cell line. Importantly, mass spectrometry (MS) and immunoprecipitation experiments verified the interaction between LOXL2 and Snail1/HDAC2 proteins, providing novel insights into the functional mechanisms of LOXL2 in tumor progression.

Patients and methods

Patients and tissue samples

We randomly enrolled 65 paraffin-embedded glioma tissues obtained from Qianfoshan Hospital Affiliated to Shandong University. Another 8 freshly isolated normal brain tissues and 13 glioma tissues were collected and stored at −80°C until use. None of the above patients had received chemotherapy or radiotherapy prior to surgery. All diagnoses were based on histological examination by the Department of Pathology according to the WHO criteria. This study was approved by the Human Ethics Committee of Qianfoshan Hospital. Written informed consent authorizing the collection and use of tissue samples for research purposes was obtained from all patients. The patients were retrospectively followed up, and the retrieved clinicopathological characteristics are summarized in Table 1.

Immunohistochemically (IHC) staining and IHC evaluation

To determine the protein expression and cellular localization of LOXL2, a 4 µm section of each tumor specimen was subjected to IHC analysis. The slides were deparaffinized, rehydrated, and treated with 3% H2O2 in methanol for 15 min to inhibit endogenous peroxidase. After blocking with 10% nonimmunogenic goat serum at room temperature for 30 min, slides were incubated with rabbit anti-LOXL2 polyclonal antibody (ab96233, Abcam, Cambridge, UK) for 30 min, slides were incubated with rabbit anti-LOXL2 polyclonal antibody (ab96233, Abcam, Cambridge, UK) overnight at 4°C. PBS incubation was parallelly conducted as the negative control. Immunoreactivity was assessed with a 2-step assay kit (PV-6001, ZSGB-Bio, Beijing, People’s Republic of China) and a DAB IHC detection kit (ZAI9017, ZSGB-Bio) according to the manufacturer’s instructions. After counterstaining, dehydration, and mounting, 2 pathologists blinded to the clinical data were invited to evaluate the IHC results based on both staining proportion and intensity. The positive proportion was scored as 0 (0%–10%), 1 (11%–25%), 2 (26%–50%), 3 (51%–75%), and 4 (75%–100%); the staining intensity was scored as 0 (negative), 1 (light yellow, weak), 2 (yellow, moderate), and 3 (dark brown, strong). The final IHC score was calculated by multiplying the 2 scores above. IHC score <8 was considered as low expression, while IHC score ≥8 was grouped into high expression.

RNA extraction and real-time quantitative PCR (RT-qPCR)

Total RNA was extracted from tissues using Trizol reagent (Takara, Tokyo, Japan) according to the manufacturer’s instruction. One microgram RNA was reverse-
cDNA product was used for RT-qPCR performed using the SYBR premix Ex Taq (Takara) on a Real-Time PCR Detection System with the following cycling program: 95°C for 10 min, 95°C for 15 sec for 40 cycles, and 60°C for 1 min. GAPDH was parallelly tested as an internal reference. The primers were as follows:

- GAPDH, forward, 5'-ATGGGGAGGGTCGACGTT-3',
- reverse, 5'-GGGGTCAATGATGGCCAACAATA-3';
- LOXL2, forward, 5'-ACATGTACCGCCATGACATCGACT-3',
- reverse, 5'-TGAAGGAACACCTATGTGGCAGT-3'.

**Western blot**

The tissues or cells were lysed in RIPA buffer containing 50 mM Tris-HCl (pH 7.5), 150 mM NaCl, 5 mM EDTA, 0.5% NP-40 (Sigma, Kawasaki, Japan), 5 mM dithiothreitol, 10 mM NaF, protease, and phosphatase inhibitor cocktail (Thermo Fisher Scientific, Pittsburgh, PA, USA). The protein concentration was determined using a BCA assay kit (Biorad, Berkeley, CA, USA). Approximately 20 μg protein was subjected to sodium dodecyl sulfate–polyacrylamide gel electrophoresis and transferred to a PVDF membrane (Thermo Fisher Scientific). After blocking with 5% nonfat milk at room temperature for 1 h, the membrane was incubated with corresponding primary antibodies (LOXL2, Sna1l, E-cadherin, phosphor-Src, Src, phosphor-FAK, FAK, HDAC2, and Snail1, E-cadherin, phosphor-Src, Src, phosphor-FAK, FAK, HDAC2, and β-tublin) at 4°C overnight. Immunoblotting was conducted with another incubation with secondary antibodies conjugated to horseradish peroxidase. Immunoreactivity was visualized with X-ray film (Fujiﬁlm, Tokyo, Japan) using ECL-Plus detection reagents (Santa Cruz Biotechnology, Santa Cruz, CA, USA).

**Cell culture and transfection**

Human normal cortical cell line (HCN-2) and 3 different glioma cell lines (U87-MG, U251, and U118-MG) were obtained from the American Type Culture Collection (Shanghai, People’s Republic of China). Cells were cultured in Dulbecco’s Modified Eagle’s Medium (Thermo Fisher Scientiﬁc) supplemented with 10% fetal bovine serum (Gibco, Life Technologies, Carlsbad, CA, USA) and maintained at 37°C in a humidified chamber containing 5% CO₂.

HA-tagged LOXL2, GFP-tagged LOXL2, and YFP-tagged Sna1l plasmids in pCDNA3.1 vector were constructed by Sangon Biotech (Shanghai, People’s Republic of China) and conﬁrmed by DNA sequence. For knockdown experiments, siRNA was synthesized by GenePharma (Shanghai, People’s Republic of China) with the following sequence: LOXL2: 5'-CAGUCUAUUUAUGUCACAU-3'; negative control: 5'-UUCUCCGAACGUGACGU-3'.

**CCK-8 proliferation assay**

At 24 h after transfection, cells were seeded into 96-well plates (5×10³ cells per well) and cultured at 37°C with 5% CO₂. At 1, 2, 3, and 4 days, 10 μL of CCK-8 solution (Beyotime, Beijing, People’s Republic of China) was added into each well. Following incubation for 1 h at 37°C, the absorbance of each well was measured at 450 nm wavelength. The experiment was performed in triplicate and repeated thrice.

**Migration and invasion assay**

Transwell chambers (Corning Inc., Corning, NY, USA) with or without Matrigel (BD Bioscience, San Jose, CA, USA) coating were used to perform migration and invasion assays, respectively. Briefly, transfected cells were cultured in serum-free medium in the upper chambers (5×10³ cells per chamber), while the lower chamber contained 10% fetal bovine serum-supplemented medium. After 48 h of culture, Transwell membranes were ﬁxed with methanol and stained with crystal violet. Noninvaded cells on the upper side of the membrane were gently wiped off, and the stained cells on the lower side were quantified under a microscope. The average number of invaded cells was calculated by counting 5 visual ﬁelds per chamber. Three independent experiments were conducted in triplicate.

**Immunoprecipitation and MS**

To identify interaction partners of LOXL2, we performed HA-affinity immunoprecipitation for U87-MG cells transfected with HA-LOXL2 plasmid. Briefly, transfected cells were harvested and lysed in lysis buffer containing 50 mM HEPES (pH 7.5), 150 mM NaCl, 1 mM EDTA, 50 mM NaF, 1.5 mM Na₂VO₄, 10 mM β-glycerophosphate, and protease inhibitor cocktail. After centrifugation at 13,000×g at 4°C for 15 min, supernatants were mixed with HA-affinity beads (Santa Cruz Biotechnology) and incubated overnight at 4°C. HA-affinity beads were then washed with lysis buffer thrice. Finally, the binding proteins were eluted with synthesized HA peptide (1 mg/mL), which were subjected to MS analysis and Western blot.
For MS analysis, the immunoprecipitated samples were
digested with trypsin and tested using shotgun strategy using
a tandem MS Q Exactive™ Plus (Thermo Fisher Scientific)
coupled online to an ultra performance liquid chromatogra-
phy system. For MS scans, the m/z scan range was set from
250 to 1,500. The obtained MS/MS data were processed using
the Mascot search engine (Matrixscience, London, UK) and
searched against SwissProt_human database as well as the
reverse decoy database.

Statistics
All statistical analyses were performed using SPSS 20.0
(IBM Corporation, Armonk, NY, USA). The correlations
between expression levels of LOXL2 and patients’ char-
acteristics were tested by χ²-test. Survival analysis and
univariate analysis were assessed by Kaplan–Meier method
and compared by log-rank test. Multivariate Cox regression
analysis was used to identify independent prognostic factors
using a forward stepwise approach. P<0.05 was considered
statistically significant.

Results
Patient characteristics
The entire cohort contained 41 male and 24 female patients,
with a median age of 49 years. Thirty-one patients (47.69%)
were suffering from WHO grade II, 22 (33.85%) had
grade III, and 12 (18.46%) had grade IV tumor. The informa-
tion on tumor size and Karnofsky performance score was
also retrieved (Table 1). The median overall survival time
was 41 months (range, 4–74 months), and there were 12
survivors by the end of follow-up.

High expression of LOXL2 is associated
with advanced tumor progression
LOXL2 showed low and negative staining in normal brain
tissues (Figure 1A). In glioma tumor cells, LOXL2 protein
mainly located in the cytoplasm and ECM, but also showed
detectable staining in the nucleus (Figure 1B). By RT-qPCR,
we found that LOXL2 mRNA was expressed higher in glioma
tissues than that in normal brain tissues (Figure 1C). Simul-
taneously, we evaluated its protein level in fresh resected
tissues, revealing an elevated protein expression than
in normal brain tissues (Figure 1D).

Thus, we were interested in exploring whether higher
LOXL2 was associated with glioma progression. By sub-
grouping patients into low LOXL2 group and high LOXL2
group, χ²-test showed that LOXL2 was positively correlated
with tumor size (P=0.006, Table 1). Additionally, higher
immunoreactivity was seen in grade III and grade IV tumors
(P=0.039), compared with grade II. There was no significant
correlation between LOXL2 protein expression and patient
gender, age, or Karnofsky score (Table 1).

LOXL2 is an independent prognostic
factor in glioma patients
Given that a significant statistical association between
LOXL2 level and disease progression was observed, we
plotted Kaplan–Meier survival curves according to dif-
ferent clinicopathological characteristics (Figure 2). By
univariate regression analysis, we identified that higher
LOXL2 protein expression was an unfavorable parameter
affecting patients’ survival (mean survival time 29.11±4.71
vs 47.75±3.18 months, P=0.003, Table 2), confirming the
association between LOXL2 and tumor progression. Other
conventional prognostic factors included tumor size and
WHO grade (P=0.048 and P=0.001, respectively).

To further explore the clinical significance of LOXL2,
we performed multivariate Cox regression analysis with
tumor size, WHO grade, and LOXL2 expression level
(Table 3). Among them, advanced WHO grade led to a
significantly worse prognosis with HR of 2.813 (95%
CI=1.561–5.069, P=0.001). Besides, LOXL2 also acted
as an independent prognostic factor in glioma patients
(HR=2.119, 95% CI=1.189–3.776, P=0.011). Tumor size
showed no statistical significance in terms of multivariate
analysis.

LOXL2 promotes proliferation, migration,
and invasion of U87-MG cells
Since LOXL2 overexpression was observed in glioma
tissues, our next question was whether LOXL2 had a direct
functional role in facilitating glioma growth or metastasis.
By testing the endogenous protein expression levels of
LOXL2 in a normal cortical cell line (HCN-2) and in 3 dif-
ferrrent glioma cell lines (U87-MG, U251, and U118-MG),
we found that LOXL2 was significantly higher expressed in
U87-MG and U118-MG cells compared to normal HCN-2
cells (Figure 3A). Due to the moderate expression level of
LOXL2 in U87-MG cells, we chose this cell line to per-
form further silencing and overexpressing studies using the
FuGENE 6 reagent. CCK-8 assay indicated that LOXL2
knockdown significantly inhibited cell proliferation, while
LOXL2 overexpression enhanced cell viability (Figure 3B).
In addition, Transwell and Matrigel–Transwell analyses were
performed to evaluate whether LOXL2 affected cell migra-
tion or invasion. Our results showed that overexpression
of LOXL2 led to a significant increase of migrated as well
as invaded cells, and silencing of LOXL2 attenuated these
High LOXL2 indicates poor glioma prognosis

processes (Figure 3C and D). These findings indicated that LOXL2 might play a tumor-promoting role in glioma.

Furthermore, Western blot analysis revealed that LOXL2 can inhibit E-cadherin level while upregulating Snail1 expression (Figure 3E), which was consistent with the results of another study. Interestingly, we also found that intracellular LOXL2 can positively regulate the phosphorylation levels of Src and FAK proteins without affecting the total protein levels. Similar signaling pathways were reported for secreted LOXL2 in gastric cancer.14

Figure 1 LOXL2 shows a higher expression level in glioma tissues.

Notes: (A) Representative negative staining of LOXL2 in normal brain tissue. (B) Representative high expression of LOXL2 in glioma tissue (male, 22 years old, WHO grade III). (C) RT-qPCR results of LOXL2-mRNA expression in normal brain tissues (n=8) and glioma tissues (n=13), showing a higher LOXL2-mRNA level in glioma (P<0.05). (D) The protein expression of LOXL2 was tested in 8 paired freshly resected normal brain tissues (N) and glioma tissues (T) by Western blot, and glioma LOXL2 showed a higher protein level than normal brain tissues in 75.0% (6/8) paired samples. Magnification 400×. Scale bar, 50 μm.

LOXL2 downregulates E-cadherin by interacting and stabilizing Snail1/HDAC2 proteins

To date, the mechanism by which LOXL2 regulates Snail1, E-cadherin, and other downstream proteins is unclear. We conducted MS experiments to detect the interactome of LOXL2 protein in U87-MG cells. By searching against SwissProt_human database, we identified Snail1 protein and HDAC2 (Figure 4A) as novel binding partners of LOXL2. It has been reported that Snail1 can recruit HDAC1/HDAC2 complex and subsequently repress E-cadherin signaling in pancreatic cancer cells and HEK 293T cells. Therefore, we suspected that LOXL2 may also participate in Snail/HDAC complex formation or stabilization. Consistent with

Discussion

LOXL2 was first reported as a collagen cross-linking enzyme, which can catalyze lysyl oxidation. Accumulating evidence showed the diverse cellular localization and functions of LOXL2. For example, it can cross-link the proteins in ECM by catalyzing oxidative deamination of peptidyl-lysine residues. Secreted LOXL2 also showed its effects by stimulating surrounding cells, such as by activating fibroblasts and promoting gastric cancer cell metastasis. Besides ECM, LOXL2 is also localized in the cytoplasm, where it regulates cell plasticity and polarity. In addition, LOXL2 plays roles in cell nucleus by modulating Snail-related signaling and transcriptional process. Importantly, LOXL2 shows tumor-promoting functions in gastric cancer, breast cancer, hepatocellular carcinoma, and lung squamous cell carcinoma. However, the high diversity of LOXL2 function may result in paradoxical effects in different tissues or cell types.

Here in the current study, we initially found that the mRNA and protein levels of LOXL2 in clinical glioma tissues were higher than those in normal brain tissues. As demonstrated by statistical analysis, LOXL2 is an independent unfavorable biomarker for glioma patients. Since LOXL2 exhibited upregulated expression in patients with advanced tumor grade, we performed cellular studies to evaluate its oncogenic roles. Consistent with other tumor types, LOXL2 overexpression significantly enhanced glioma tumor cell proliferation and invasion, indicating its potential as a novel drug target. Taking into consideration the fact that LOXL2 has complex functions, we next aimed to identify its global binding partners to better elucidate its signaling network.

HDAC1 and HDAC2 are well-known tumor suppression proteins. Previous studies showed the existence of a HDAC1/HDAC2/Snail complex, which can inhibit E-cadherin signaling in pancreatic cancer. Besides HDAC1/HDAC2, Snail1 protein was also reported to be directly regulated by LOXL2, thus exerting transcriptional and epigenetic functions. Notably, we identified the existence of both Snail1 and HDAC2 in LOXL2 protein complexes by using immunoprecipitation and MS strategies. Further IHC data demonstrated a statistically significant correlation between HDAC2 and LOXL2 expression in glioma tissues. Therefore, it is highly likely that LOXL2 can recruit HDAC2 to interact with Snail1, forming a functional heterotrimer, or even hereotetramer with the involvement of HDAC1, to inhibit E-cadherin signaling. However, whether and how this protein complex is assembled needs further structural information.

Last but not least, our data suggested another signaling pathway downstream of LOXL2, which is accomplished by phosphorylation of Src and FAK protein complex. Src and FAK proteins can both be activated upon phosphorylation, subsequently promoting cell proliferation via a wide range

of molecular effectors. Therefore, LOXL2 may promote tumor progression of glioma by synergistic multiple signaling pathways.

**Conclusion**

In conclusion, our data suggested that high LOXL2 expression indicated poor overall survival of glioma patients, and LOXL2 may exert tumor-promoting effects by enhancing Src and E-cadherin signaling pathways.

**Disclosure**
