Abstract: Breast cancer is the leading cause of death in women globally. The human epidermal growth factor receptor 2 (HER2)-positive breast cancer is often associated with poor prognosis and high mortality. Even though anti-HER2 monoclonal antibodies have improved the clinical outcome, resistance to the antibody therapy becomes a major obstacle in the treatment of HER2-positive breast cancer patients. Alternative approaches are therefore needed. HER2-specific vaccines have been developed to trigger patient’s immune system against HER2-positive breast cancer. This article describes the development of novel HER2-specific exosome (EXO)-T vaccine using polyclonal CD4\(^+\) T cells armed with HER2-specific dendritic cell-released EXO and demonstrates its therapeutic effect against HER2-positive tumor in double-transgenic HER2/HLA-A2 mice with HER2-specific self-immune tolerance. Therefore, our novel HER2-specific EXO-T vaccines are likely to assist in the treatment of HER2-positive breast cancer patients.

Keywords: EXO-T vaccine, polyclonal CD4\(^+\), T cell, HER2, exosome, breast cancer

Introduction

Breast cancer is the most commonly diagnosed cancer and the second most common cause of cancer death in women in the USA.\(^1,3\) The human epidermal growth factor receptor 2 (HER2) oncogene encodes for a 185 kD transmembrane glycoprotein receptor with intracellular tyrosine kinase activity.\(^4\) It belongs to the human EGFR family including HER1, HER2, HER3, and HER4 that control breast cancer cell proliferation, migration, and invasion.\(^5\) Amplification of HER2 is observed in approximately 20% of human breast cancers.\(^6-8\) HER2-positive breast cancer is associated with increased rates of metastasis, reduced time to relapse, poorer prognosis, and higher mortality.\(^6-8\) Development of HER2-targeted immunotherapeutics such as HER2-specific monoclonal antibodies trastuzumab and lapatinib has greatly improved therapeutic outcome.\(^9,10\) Trastuzumab is remarkably effective both as monotherapy and in combination with cytotoxic chemotherapy in patients with HER2-positive metastatic breast cancer. However, most patients sooner or later develop resistance to trastuzumab during trastuzumab treatment,\(^11,12\) warranting the development of other effective HER2-targeted therapies.

Three signals in CD8\(^+\) T cell response

CD8\(^+\) cytotoxic T lymphocytes (CTLs) are responsible for adaptive immune responses against tumor. After antigen presentation to naïve CD8\(^+\) T cells by antigen-presenting cells, such as dendritic cells (DCs), CD8\(^+\) T cells start to proliferate and become cytotoxic effectors capable of inducing cancer cell death via secreting cytokines (tumor necrosis factor-\(\alpha\) and interferon-\(\gamma\)) and cytolytic granzyme-B.\(^13\) There are three conventional signals
participating in induction of CD8$^+$ CTL immunity. The first signal is derived from the antigen peptide-presenting major histocompatibility complexes (pMHC-I) on DCs, which recognize the antigen-specific T-cell receptors (TCRs) on CD8$^+$ T cells (Figure 1A). The second costimulatory signal is the interaction of DC’s costimulatory CD80 molecules with CD28 ligands on CD8$^+$ T cells (Figure 1A). The third signal represents the innate inflammatory cytokines such as IL-12 and IFN-α stimulating CD8$^+$ T cells (Figure 1A). The first two signals are responsible for naïve CD8$^+$ T-cell proliferation, while IL-12 and IFN-α are in charge of the development of CTL effector functions. Apart from those signals, IL-15 secreted by DCs induces T-cell memory formation.

**Exosome-targeted polyclonal CD4$^+$ T cell vaccine**

Some HER2-positive breast cancer patients have been found to develop spontaneous anti-HER2-specific immunity with both antibody and CD8$^+$ T-cell responses, indicating that HER2 is an immunogenic target for the development

Notes: (A) Conventional three signals in APC-stimulated CD8$^+$ T-cell responses, including 1) antigen peptide/major histocompatibility complex-I (pMHC-I)/TCR, 2) costimulatory CD80/CD28, and 3) cytokines IL-12, IL-15 (for T-cell memory formation). (B) Distinct three signals derived from novel EXO-T vaccine include 1) exosomal pMHC-I/TCR, 2) exosomal CD80/CD28 and T-cell CD40L/CD40 (for T-cell memory formation), and 3) T-cell cytokine IL-2 (for T-cell proliferation). (C) Conversion of exhausted CD8$^+$ CTLs within tumor by EXO-T cells via T cell CD40L/CD40-activated mTORC1 pathway.

Abbreviations: APC, antigen-presenting cell; CTLs, cytotoxic T lymphocytes; EXO, exosome; IFN-γ, interferon-γ; TCR, T-cell receptor.
of anti-HER2 vaccines to stimulate patient’s own immune system against breast cancer. HER2-specific vaccines using HER2-specific peptides, proteins, DNA, or DCs have been developed, but mostly showing relatively limited antitumor effects.\textsuperscript{16}

Exosomes (EXOs) are small vesicles of 50–100 nm in diameter secreted by budding from the cellular membrane.\textsuperscript{17} DC-released EXOs are enriched in immunological molecules important for DC’s stimulatory machinery.\textsuperscript{17} Similar to the previous adoptive engineered CD8\textsuperscript{+} T-cell therapy using active polyclonal CD8\textsuperscript{+} T cells engineered to express tumor-specific TCR,\textsuperscript{18} we developed novel CD4\textsuperscript{+} T-cell-based (EXO-T) vaccines using active polyclonal CD4\textsuperscript{+} T cells armed with tumor-specific DC-released EXOs.\textsuperscript{19–25} In the former one, polyclonal CD8\textsuperscript{+} T cells are genetically engineered to express tumor-specific TCRs containing signaling domain of CD3 zeta-chain or to express chimeric antigen receptor containing single-chain Fv fused to signaling domain of T-cell costimulatory molecules such as 41BB leading to the currently well-known chimeric antigen receptor-T therapy.\textsuperscript{26} In the latter one, EXO-T vaccines prepared by simply incubation of ConA-stimulated polyclonal CD4\textsuperscript{+} T cells with antigen-specific DC-released EXOs. The polyclonal CD4\textsuperscript{+} T cells took up antigen-specific DC-released EXOs via interaction of exosomal CD54 with T cell lymphocyte function-associated antigen 1, leading to the expression of exosomal surface molecules (pMHC-I and CD80) on CD4\textsuperscript{+} T cells via vesicle internalization/recycling and direct membrane fusion.\textsuperscript{19} As a result, the polyclonal CD4\textsuperscript{+} T cells phenotypically armed with antigen-specific exosomal pMHC-I complexes and exosomal CD80 molecule became antigen-specific EXO-T vaccines.\textsuperscript{19–25}

Compared with vaccination of DCs presenting the three conventional signals, EXO-T vaccines stimulate CD8\textsuperscript{+} T-cell responses via three distinct signals namely 1) acquired exosomal pMHC-I, 2) acquired exosomal CD80 and CD4\textsuperscript{+} T cell CD40L, and 3) CD4\textsuperscript{+} T cell IL-2 (Figure 1B). EXO-T vaccines have been found to stimulate potent CD4\textsuperscript{+} T-cell-independent CTL responses\textsuperscript{19–25} and to promote CTL memory via CD4\textsuperscript{+} T cell CD40L signaling.\textsuperscript{20}

CD8\textsuperscript{+} CTL exhaustion with overexpression of inhibitory molecules such as PD-1, Tim-3, and LAG-3 and with functional deficiency in the production of effector cytokine IFN-\gamma and effector cytolytic granzyme-B is a state of dysfunction that commonly occurs during cancer and infection diseases, which leads to failure in reducing viral or tumor load.\textsuperscript{27} We demonstrated that EXO-T vaccine was able to convert CTL exhaustion in chronic infection via CD4\textsuperscript{+} T cell CD40L signaling-induced activation of mTORC1 pathway, leading to CTL proliferation, IFN-\gamma production, and rescuing CTL cytotoxic effect.\textsuperscript{21} Because tumor-specific effector CTLs that undergo tumor tolerogenic microenvironment also become terminally differentiated into exhausted CTLs without any antitumor properties,\textsuperscript{28} our novel EXO-T vaccine may thus be able to exert its conversional effect on exhausted CTLs within tumors (Figure 1C).

**HER2-Exo vaccine**

We have recently developed Neu-specific (the rat’s form of human HER2) or HER2-specific EXO-T vaccines (Neu-Texo and HER2-Exo) using active polyclonal CD4\textsuperscript{+} T cells with uptake of Neu- or HER2-specific DC-released EXOs.\textsuperscript{22} We demonstrated that Neu-specific EXO-T vaccine stimulated Neu-specific CTL responses against Neu-expressing breast cancer Tg1-1 in transgenic FVB/neuN mice, while HER2-specific EXO-T vaccine stimulated HER2-specific immunity against HER2/HLA-A2-expressing BL6-10\textsubscript{A2/HER2} melanoma in double transgenic HER2/HLA-A2 mice with HER2-specific self-immune tolerance.\textsuperscript{29} In addition, HER2-specific EXO-T-stimulated CTLs also showed potent therapeutic effect against both HER2-positive breast cancer T47D and trastuzumab-resistant HER2-positive breast cancer BT474 in athymic nude mice.\textsuperscript{22} Heterologous DNA vaccines composed of fused cDNA fragments encoding chimeric DH2-terminal human HER2 and COOH-terminal rat Neu sequences have been reported to stimulate stronger antibody responses and protective antitumor immunity than either HER2 or Neu DNA vaccine in transgenic mice with HER2-specific self-immune tolerance.\textsuperscript{29,30} These findings prompted us to have a hypothesis that heterologous HER2/Neu-specific T cell vaccine may induce more effective anti-HER2 CTL responses. To test this hypothesis, we construct an adenoviral vector (Ad\textsuperscript{V}_{HER2/Neu}) expressing a fused cDNA fragment (Hu/Rt HER2/Neu) encoding chimeric NH2-terminal human HER2 and COOH-terminal rat (Rt) Neu sequence by recombinant DNA technology.\textsuperscript{31} Based on Ad\textsuperscript{V}_{HER2/Neu}, we further generated heterologous HuRt HER2/Neu-specific EXO-T vaccine (HuRt-Texo) using polyclonal CD4\textsuperscript{+} T cells with uptake of Ad\textsuperscript{V}_{HER2/Neu}-transfected DC-release EXOs.\textsuperscript{31} We demonstrated that heterologous HuRt-Texo vaccine, in comparison with homologous HER2-Texo one, more strongly stimulated both HER-2-specific antibody and CTL responses leading to complete inhibition of growth of established lung metastasis of HER2-expressing 4T1\textsubscript{HER2} breast cancer in BALB/c mice and complete protection of transgenic HLA-A2/HER2 mice from growth of HLA-A2/HER2-expressing BL6-10\textsubscript{A2/HER2} melanoma in double transgenic HER2/HLA-A2 mice.\textsuperscript{31} In addition, HuRt-EXO-stimulated CTLs are also able to
eradicate established trastuzumab-resistant BT474 breast cancer in athymic nude mice.\textsuperscript{31}

The long-term goal is to develop human therapeutic HER2/Neu-specific EXO-T vaccine using autologous polyclonal T cells with uptake of HER2/Neu-specific autologous DC (DC\textsubscript{HER2/Neu})-released EXOs as a new novel personalized vaccine for breast cancer.\textsuperscript{32} The human autologous DCs derived from peripheral blood mononocytes activated in culture medium by granulocyte-macrophage colony-stimulating factor, IL-4, and tumor necrosis factor-\textalpha; followed by infection with HER2/Neu-specific adenoviral vector (Ad\textsubscript{HER2/Neu}) to form DC\textsubscript{HER2/Neu}.\textsuperscript{22}

**Conclusion**

Taken together, our data indicate that HER2-specific EXO-T vaccine circumventing HER2 tolerance may provide a new therapeutic alternative for trastuzumab-resistant breast cancer patients with HER2-specific self-immune tolerance. Because many other human cancer antigens were also identified including $\alpha$-fetal protein, carcinoembryonic antigen, CA125, CA19-9, and prostate-specific antigen in various types of cancer,\textsuperscript{34} novel EXO-T vaccines similarly generated by arming polyclonal CD4$^+$ T cells with different tumor antigen-specific EXOs are thus likely to become a useful therapeutic strategy to assist in the treatment of various cancers.
