Objective: Intrathecal dexmedetomidine (DEX) has been used to prevent shivering in patients undergoing cesarean section. The aim of this meta-analysis was to evaluate whether intrathecal DEX could prevent shivering in cesarean section after spinal anesthesia.

Methods: We searched PubMed, Embase, Web of Science, and the Cochrane Library for randomized controlled trials (RCTs) comparing intrathecal DEX in cesarean section after spinal anesthesia with placebo and reporting on shivering, postoperative nausea and vomiting (PONV), hypotension, and bradycardia. Trial sequential analysis (TSA) was also carried out for RCTs comparing DEX with placebo. This meta-analysis has been registered on PROSPERO, and the registration number is CRD42017071640.

Results: Six randomized clinical trials comparing 360 patients were included in this study. Compared with placebo, intrathecal DEX significantly reduced the incidence of shivering (risk ratio [RR]=0.40; 95% CI [0.26, 0.62]; $P<0.0001$). No significant difference was found in the incidence of PONV (RR=1.34; 95% CI [0.82, 2.18]; $P=0.24$), hypotension (RR=1.09; 95% CI [0.84, 1.42]; $P=0.50$), or bradycardia (RR=1.55; 95% CI [0.54, 4.42]; $P=0.42$). However, no firm conclusions can be made based on the results of all outcomes according to the TSA.

Conclusion: This meta-analysis found that intrathecal DEX could prevent shivering in cesarean section after spinal anesthesia and did not induce PONV, hypotension, or bradycardia. However, firm conclusions cannot be made until more studies are conducted.

Keywords: dexmedetomidine, cesarean section, spinal anesthesia, meta-analysis, trial sequential analysis, adverse effect

Introduction

Spinal anesthesia has been widely used to provide anesthesia and analgesia for cesarean section, which allows a patient to remain awake for the birth of her baby while avoiding the risks of general anesthesia.¹⁻³ Even though the risk of spinal anesthesia is lower than that of general anesthesia, the adverse events caused by spinal anesthesia, such as shivering, are still present during surgical procedures, causing discomfort for the patients.^{4,5}

The incidence of shivering is up to 55% according to a previously published study.⁶ Shivering may lead to increased oxygen consumption and negative effects on pulse, oxygen saturation, and blood pressure. Severe adverse effects may occur if the patient has cardiopulmonary insufficiency.^{6,7}

Dexmedetomidine (DEX), as a highly selective α -2 adrenoreceptor agonist, can provide some beneficial effects when administered through the spinal route, such as sedation, analgesia, antianxiety effects, and increased threshold of shivering.^{8,9} Some randomized controlled trials (RCTs) have been conducted to estimate the effects of intrathecal DEX on shivering. However, the effect of intrathecal DEX on shivering in cesarean section after spinal anesthesia remains controversial. Therefore, we conducted this meta-analysis from relevant studies to evaluate the effects of intrathecal DEX on shivering in cesarean section after spinal anesthesia. Additionally, trial sequential analysis (TSA) was carried out for RCTs comparing DEX with placebo.

Subjects and methods

Protocol and registration

We followed the recommendations of the Cochrane Handbook for Systematic Reviews of Interventions¹⁰ and the PRISMA recommendations to conduct the present meta-analysis.¹¹ The protocol has been registered in the PROSPERO international database under number CRD42017071640.

Search strategy

Two authors searched PubMed, Embase, Web of Science, and the Cochrane Library using search terms (“dexmedetomidine”, “cesarean section”, “cesarean delivery”, “spinal anesthesia”) up to March 31, 2018, without language restriction. We also manually searched for the references of the identified trials and systematic reviews to identify any potentially relevant trials. Titles, abstracts, and full texts of potentially relevant articles were screened after excluding duplicated ones.

Eligibility criteria

The following were the eligibility criteria:

- Participants: adult patients undergoing cesarean section after spinal anesthesia.
- Interventions: any study was considered if DEX was delivered via intrathecal route.
- Comparisons: patients who were exposed to placebo.
- Outcomes: at least one of the following outcomes was reported in the studies: incidence of shivering, postoperative nausea and vomiting (PONV), hypotension, or bradycardia.
- Study design: only RCTs were regarded as eligible for this meta-analysis.

Study selection and data extraction

Two authors independently identified the studies for inclusion according to the eligibility criteria. Any disagreement was resolved by consensus. The following data were extracted from each included study: first author, country, year of publication, number of participants, intervention details, and trial characteristics. The primary outcome was shivering, and the secondary outcomes included PONV, hypotension, and bradycardia.

Assessment of study quality

Two authors independently assessed the risk of bias in the included studies. The following factors were assessed according to the Cochrane risk of bias tool for each study:¹² 1) random sequence generation; 2) allocation concealment; 3) blinding of participants and personnel; 4) blinding of outcome assessors; 5) incomplete outcome data; and 6) selective outcome reporting and other bias. Trials were classified as having low, unclear, or high risk of bias on each domain. Trials were considered to have a high risk of bias if one or more of these domains were scored as unclear or high risk of bias.

Statistical analyses

All the statistical analyses were conducted using Review Manager, version 5.3 (The Nordic Cochrane Center, The Cochrane Collaboration, Copenhagen, 2014). Dichotomous outcomes were reported by the risk ratio (RR) and 95% CI. Heterogeneity was assessed with the I^2 statistic.¹³ We selected the random-effects model to calculate pooled effects, regardless of whether I^2 was $\geq 50\%$.

Subgroup analysis and sensitivity analysis were performed on factors that may have contributed to the heterogeneity. Subgroup analysis was carried out according to the drug dosage (5 and 10 μg). Sensitivity analysis was performed by using both the random-effects and fixed-effects analysis models.¹⁴ Sensitivity analysis was also performed by removing one study at a time to assess the effect of each study on the overall effect size.

TSA

The reliability and conclusiveness of the available evidence were examined by TSA, which can reduce false-positive results caused by multiple testing and sparse data.^{15,16} We calculated the required information size (RIS) and the trial sequential monitoring boundaries for all outcomes.

The variance was calculated from the data obtained from the included studies. If the cumulative Z curve crossed the TSA boundary, a sufficient level of evidence for the anticipated intervention effect may have been reached and no further studies are needed. However, if the Z curve failed to cross the TSA boundaries and the RIS has not been reached, evidence to reach a conclusion is insufficient. We used two-sided tests with a type I error of 5%, a power of 80%, and a relative risk reduction of 20% to calculate the RIS.¹⁷

Results

Trial selection

Figure 1 shows a summary of the study selection process. We identified 104 studies through database searching. After excluding duplicate references and reviewing titles and abstracts, we selected 13 studies for full-text evaluation. Of these, seven trials did not meet the inclusion criteria or the

exclusion criteria. The main reasons for exclusion included that the study was not randomized (n=1), that DEX was not given by intrathecal route (n=5), or that the study did not report outcomes that we needed (n=1). Finally, six studies were included.^{18–23}

Characteristics and quality of included studies

Table 1 shows the details of all the studies included in the meta-analysis. All studies used bupivacaine as the local anesthetic. However, the dose of DEX was different between the studies. In all, 10 µg of DEX was used in two studies and 5 µg of DEX was used in the other four trials. Two authors independently evaluated the quality of all the RCTs. All the six studies were classified as low risk of bias, and details of the risk of bias for all of the included studies are shown in Figure 2.

Figure 1 PRISMA flowchart of the included studies.

Table 1 Characteristics of all the trials included in the meta-analysis

Study	Country	No of participants		Administration route	Intervention	
		DEX	Control		Experimental group	Control group
Li et al ¹⁸	China	21	21	Spinal	Bupivacaine 4 mL (10 mg)+DEX 10 µg	Bupivacaine 4 mL (10 mg)
Sun et al ¹⁹	China	30	30	Spinal	Bupivacaine 0.5% 2 mL (10 mg)+DEX 10 µg	Bupivacaine 0.5% 2 mL (10 mg)+1.0 mL 0.9% saline
Qi et al ²⁰	China	39	39	Spinal	Bupivacaine 0.5% 2 mL+DEX 5 µg	Bupivacaine 0.5% 2.0 mL
Nasseri et al ²¹	Iran	25	25	Spinal	Bupivacaine 0.5% 12.5 mg+DEX 5 µg	Bupivacaine 0.5% 12.5 mg+0.5 mL 0.9% saline
He et al ²²	China	45	45	Spinal	Bupivacaine 0.5% 2.5 mL+DEX 5 µg	Bupivacaine 0.5% 2.5 mL+0.5 mL 0.9% saline

Abbreviation: DEX, dexmedetomidine.

Outcomes of the meta-analysis

Shivering

All studies reported the incidence of shivering. Data extracted from relevant studies indicated that the addition of DEX

significantly reduced the incidence of shivering (RR=0.40, 95% CI [0.26, 0.62]; Figure 3) according to conventional meta-analysis. The TSA indicated that the Z curve failed to cross the TSA boundary and did not reach the RIS but crossed the conventional boundary (Figure 4).

Subgroup analysis showed that the only the application of DEX 5 µg (RR=0.41, 95% CI [0.26, 0.63]) was significantly more effective than that of placebo for the prevention of shivering, while no difference was found between the two groups when DEX 10 µg was injected.

Heterogeneity was found in the incidence of shivering; therefore, sensitivity analysis was performed. By removing one study at a time, the sensitivity analysis had no effect on the result.

PONV

All six studies reported PONV. It was found that the addition of DEX did not reduce the risk of PONV (RR=1.34, 95% CI [0.82, 2.18]; Figure 5). The TSA indicated that the Z curve failed to cross the conventional boundary or the TSA boundary (Figure 6).

Hypotension

Data from five studies involving 320 participants showed that the risk of hypotension was similar in the two groups (RR=1.09, 95% CI [0.84, 1.42]; Figure 7). The TSA indicated that the Z curve failed to cross the conventional boundary or the TSA boundary (Figure 8).

Bradycardia

Five studies reported data about the occurrence of bradycardia, which showed that the rate of bradycardia in the DEX group was similar to that in the control group (RR=1.55,

95% CI [0.54, 4.42]; Figure 9). There was too little information to conduct the TSA boundary.

Discussion

For the present study, we retrieved six RCTs to investigate the effect of DEX as a neuraxial adjuvant in cesarean section.

We found that spinal administration of DEX could effectively prevent perioperative shivering but did not increase the incidence of PONV or induce bradycardia and hypotension.

DEX is a highly selective α_2 -adrenergic receptor agonist and can provide many beneficial effects, such as sedation, analgesia, perioperative sympathectomy, and synesthetic

sparing, without depressing respiration.^{24,25} Because of these beneficial effects, DEX is widely used clinically, including for cesarean section.^{18,26} However, when administered by intravenous route, DEX can induce some negative side effects, such as bradycardia and hypotension.²⁷ To decrease side effects, some clinicians choose to decrease the dose or change the administration route. Several studies demonstrated that epidural administration of DEX could provide some beneficial effects, including sedation, analgesia, and antianxiety effects.^{24,25}

Shivering is one of the common complications of neuraxial anesthesia and causes discomfort and dissatisfaction in

patients undergoing cesarean section. It was reported⁶ that the incidence of shivering after regional anesthesia was up to 55% and the incidence in cesarean section may be even higher.²⁸ Shivering increases the consumption of oxygen and production of CO₂ and may also intensify postoperative pain.²⁹ The reasons for shivering may include suppression of spinal reflex activity, decrease in sympathetic activity, and inhibition of adrenal function.³⁰ Many studies reported that DEX could effectively reduce the incidence of shivering during neuraxial anesthesia in patients undergoing cesarean section, without any associated respiratory depression as with other antishivering drugs, such as meperidine.^{18–22} The present

meta-analysis showed the same results reported in previous clinical trials. Some studies demonstrated that DEX could increase the temperature range without triggering thermoregulatory defenses by stimulating central α_2 -adrenergic receptors, thereby decreasing the central thermoregulatory threshold for shivering.^{31–33} The antishivering effect of intrathecal DEX may be caused by decreasing the shivering threshold.³⁴ Additionally, DEX could prevent postoperative shivering by attenuating the hyperadrenergic response to perioperative stress.³⁵ The data from four studies showed that the incidence of shivering was significantly lower than that in placebo when given DEX 5 μ g, revealing that the low dosage of DEX may be more efficacious.

The present meta-analysis showed that, unlike opioids, DEX did not increase the incidence of PONV caused by cesarean section. PONV is a common complication of cesarean section. The causes for PONV during cesarean section include hypotension, visceral traction, and vagal stimulation, and among them, hypotension may be the most common cause.^{36,37} It was reported that compared with intravenous infusion, intrathecal DEX seldom induced hypotension,³⁸ which is in accordance with the meta-analysis and why spinal administration of DEX would not increase the incidence of PONV. Opioids, which are the most common neuraxial adjuvants to local anesthetics, have many disadvantages, including PONV. Several studies reported that the usage of

Figure 8 TSA evaluating the incidence of hypotension with and without DEX.

Figure 9 Forest plot for the incidence of bradycardia with and without DEX.

Abbreviations: DEX, dexmedetomidine; RR, risk ratio; M-H, Mantel-Haenszel.

DEX could reduce the demand for opioids during cesarean section.^{18,19,30} This means that DEX may not only increase the incidence of PONV but also reduce the incidence of PONV during cesarean section.

There are some potential limitations associated with the included studies that should be considered when interpreting the results of our study. First, the number of included RCTs and the sample size were small, and thus, our conclusions are still based on a relatively small number of studies. Second, since we only included published literature, the search strategy could have also affected the results of this study. Third, the doses of DEX in the retrieved trials are varied. This demonstrated that the clinical use of DEX is not strictly regulated. Fourth, most of the studies included in this meta-analysis were conducted in China, and more studies conducted in different countries are still needed to confirm our findings. Additionally, further studies should be designed to demonstrate the effect of DEX on the neonatus.

Conclusion

This study showed that intrathecal DEX reduced the risk of shivering in patients undergoing cesarean section after spinal anesthesia and did not increase the incidence of PONV, hypotension, or bradycardia. However, the TSA indicated that further trials are still needed to confirm the abovementioned findings.
