Purpose: To evaluate the association between the use of statins and/or metformin and patient survival in prostate cancer patients in Taiwan.

Subjects and methods: Newly diagnosed prostate cancer patients who had hyperlipidemia and received radiotherapy were identified from the National Health Insurance Research Database 2000–2010. The survival rate was estimated by the Kaplan–Meier method. Univariate and multivariate Cox regression analyses were performed to examine the association of mortality. Sensitivity analysis was performed to assess the risk of mortality in patients with diabetes.

Results: The study included 567 patients. Patients who used statins or metformin after prostate cancer diagnosis had longer average survival times (9.3 years and 8.1 years, respectively; P<0.001) compared with patients who persistently used or used the medicines prior to cancer diagnosis. Multivariate Cox regression analysis found that patients treated with statins after cancer diagnosis were significantly associated with a lower risk of mortality (aHR =0.24, 95% CI =0.09–0.66) compared to patients who did not use statins during the study period. Patients treated with metformin after cancer diagnosis were significantly associated more with an increased risk of mortality (aHR =6.78, 95% CI =2.45–18.77) compared to patients who did not use metformin during the study period. Sensitivity analysis revealed that the average survival time was similar among different medicine use groups in patients with diabetes.

Conclusion: The finding suggests that statins and metformin use after prostate cancer diagnosis may increase survival in patients with hyperlipidemia and radiotherapy.

Keywords: prostate cancer, metformin, statin, hyperlipidemia, mortality, survival

Introduction

Cancer has been the leading cause of death in Taiwan for more than a decade.1 Prostate cancer is ranked the fifth most common cancer in Taiwan, with the seventh highest cancer-related mortality rate.2 The incidence of prostate cancer has been rapidly increasing in the past 10 years.3

Findings from several retrospective observational studies indicate that treatment with statins or metformin can reduce prostate-specific antigen (PSA) levels.4–8 Statin use is found to be associated with a lower advanced prostate cancer risk and reduced prostate cancer-specific mortality.9 Statins are potent inhibitors of 3-hydroxy-3-methylglutaryl coenzyme A reductase, and are commonly used for treating hyperlipidemia by lowering cholesterol.9,10 Cholesterol plays a role in steroid androgens that drive prostate growth.11 In addition, rapidly growing tumor cells also require high levels of cholesterol. A number of reports suggest that statins are associated with a reduc-
tion in the incidence of prostate cancer, disease recurrence, and better overall survival in patients; however, others have found no such benefits with statin therapy.\textsuperscript{1,2–17} However, a link between cholesterol and reduction of PSA is not clear.\textsuperscript{4,5}

Metformin is a commonly used antidiabetic medication and is an insulin-sensitizing oral biguanide. Several in vitro studies suggest that the use of metformin may be protective against prostate cancer or delay disease progression.\textsuperscript{18–21} Prior studies suggest that metformin may show a benefit as adjuvant therapy to standard prostate cancer therapy, particularly in patients receiving androgen deprivation therapy (ADT).\textsuperscript{22,23} However, for metastatic castration-resistant prostate cancer, it has been suggested that metformin may not be an effective chemosensitizer.\textsuperscript{24} Furthermore, several studies have found that metformin did not improve biochemical-free or cancer-specific survival in patients treated with permanent interstitial brachytherapy.\textsuperscript{25,26} Deng et al\textsuperscript{27} suggested that there was no association between the metformin treatment and all-cause mortality or recurrence, but yet metformin therapy may decrease the incidence of prostate cancer.

The results for use of statins and/or metformin in prostate cancer were controversial and should be confirmed with further investigation. Statins and metformin are commonly used for treating hyperlipidemia.\textsuperscript{10,28} Studies exploring the association between the use of statins and/or metformin and patient survival in prostate cancer patients in Taiwan have never been reported. Thus, the current study aimed to assess associations of statins and/or metformin therapy and survival of prostate cancer patients with hyperlipidemia and radiotherapy in Taiwan. The study was a retrospective, nationwide, Taiwanese-based study using the database from the Taiwan National Health Insurance.\textsuperscript{29,30}

**Subjects and methods**

**Data source**

Taiwan launched a single-payer National Health Insurance program on March 1, 1995.\textsuperscript{29} The database of this program, called The National Health Insurance Research Database (NHIRD), contains registration files and original claim data for reimbursement. The NHIRD represents a comprehensive nationwide database that includes information since 1995 and which covers 99\% of Taiwan’s 23.74 million people, 98\% of whom are Han Chinese. The database is maintained by the National Health Research Institutes in Taiwan and provided to scientists in Taiwan for research purposes. The NHIRD databases provide excellent data sources for population-level analysis, with minimal discrepancies and biases.\textsuperscript{31}

This study was approval by the Institutional Review Board of the Third Affiliated Hospital of Sun Yat-sen University. Given the retrospective nature of this study design, the requirement for obtaining informed consent was waived.

**Study population**

A total of 5,079 males newly diagnosed with prostate cancer were identified from the NHIRD database during 2000–2010 using the appropriate International Statistical Classification of Diseases code (ICD\textsuperscript{9}=185). After excluding 3,020 patients who did not have hyperlipidemia (ICD\textsuperscript{9}=272) and 1,492 patients who did not receive radiotherapy after being diagnosed with prostate cancer, only 567 patients were included in this study (Figure 1).

**Variable definitions**

The primary outcome was overall survival. Independent variables included demographic characteristics (age), the use of medicines, such as statin (ATC code: C10AA01–C10AA05, C10AA07, and C10AA08) or/and metformin (ATC code: A10BA02), and the comorbidities, such as obesity (ICD-9-CM 278.0), diabetes mellitus (ICD-9-CM 250), and metabolic syndrome (ICD-9-CM 277.7). Furthermore, subjects with the use of statin only and metformin only were subdivided into three groups: the pre-diagnostic use group (use of statin or metformin prior to prostate cancer diagnosis), the post-diagnostic use group (use of statin or metformin after diagnosis of prostate cancer), and the persistent use group (continuous use of the medicines before and after the cancer diagnosis).

**Statistical analysis**

The continuous variable was expressed as the mean and SD. Categorical variables were expressed as counts and percentages. Kaplan–Meier survival analysis was performed for medicine use (ie, statin and/or metformin) with the endpoint of the mortality, and the statistical significance was examined using a log-rank test. In survival analysis, any cause of deaths was treated as events and survivors were treated as censored events. Univariate and multivariate Cox proportional hazards regression analyses were performed to examine the association of mortality. The multivariate Cox proportional hazards regression model was simultaneously adjusted for the baseline characteristics, including age, diabetes mellitus, hypertension, cardiovascular disease, peripheral artery disease, and atherosclerosis. Furthermore, subgroup analyses were performed for patients using statin only or metformin...
only to examine the association of mortality. In addition, a sensitivity analysis was carried out to assess the association of mortality in patients with diabetes.

All statistic assessments were two-sided and evaluated at the 0.05 level of significance. Statistical analyses were performed by IBM SPSS statistical software version 22 for Windows (IBM Corporation, Armonk, NY, USA).

**Results**

The average age of the study population was 71.8 years. A total of 213 (37.6%) patients did not use either statin or metformin, 121 (21.3%) took both drugs, 174 (30.7%) only received the statin, and 59 (10.4%) were only administered metformin. The most common comorbidities were diabetes mellitus (53.8%), hypertension (77.7%), and cardiovascular disease (66.3%). During the follow-up period, 137 deaths (24.2%) occurred in the total study population (Table 1). A higher percentage of patients with diabetes mellitus used metformin (88.1%, \( P<0.001 \)) compared with those taking statins, a combination of metformin and statins, or did not use either drug (Table S1). A greater percentage of patients with hypertension took statins (84.3%, \( P=0.046 \)) compared with not using either drug or taking both drugs. A larger percentage of patients with cardiovascular disease used only statins (73.0%, \( P=0.009 \)) compared with the other evaluated treatment regimens.

Kaplan–Meier analysis found that the average survival time for the total study population was 7.5 years (Figure 2 and Table 2). The survival time was similar for patients who did not use statins or metformin (the unused group, 7.1 years), who used both statins and metformin (the both group, 7.8 years), who only received statins (7.8 years), or who only took metformin (6.9 years) (Log-rank test, \( P=0.407 \)) (Figure 2). Multivariate Cox regression analysis indicated that, compared to the unused group, the other three groups (both, only use statins, and only use metformin) were associated with lower risk of mortality, although the differences were not significant (Table 2). Furthermore, subgroup analyses were performed in which patients were divided into three medicine use categories: persistent use, pre-diagnostic use, and post-diagnostic use. The result of Kaplan–Meier analysis showed that patients with post-diagnostic use of statin had a longer average survival time (9.3 years, Log-rank test, \( P=0.001 \))

(Table 3 and Figure 3). A similar result was also observed in patients with post-diagnostic use of metformin (8.1 years, Log-rank test, \( P<0.001 \)) (Table 3 and Figure 3).

Multivariate Cox regression analysis revealed that patients who were treated with statins after the diagnosis of prostate cancer were significantly associated with a lower risk of mortality (aHR =0.24, 95% CI =0.09–0.66, \( P<0.05 \)) compared to patients who did not use statins during the study period (Table 3). In contrast, patients who were treated with metformin before prostate cancer diagnosis were significantly associated with a higher risk of mortality (aHR =6.78, 95% CI =2.45–18.77, \( P<0.05 \)) compared to patients who did not use metformin during the study period (Table 3).

A sensitivity analysis was performed to evaluate the risk of mortality in patients with diabetes, and the results revealed that the average survival time was similar among different medicine use groups in diabetic patients (Log-rank test, \( P=0.906 \)) (Table S2). As shown in Table S3, diabetic patients who were treated with statins after the diagnosis of prostate cancer were significantly associated with a lower risk of mortality (aHR =0.24, 95% CI =0.09–0.66, \( P<0.05 \)) compared to patients who did not receive statin therapy. Furthermore, diabetic patients with pre-diagnostic use of metformin were significantly associated with a higher risk of mortality (aHR =2.57 and 2.96, respectively, Table S3) compared to those without statin therapy. More specifically, diabetic patients with persistent use and pre-diagnostic use of statins were significantly associated with a significantly higher risk of mortality (aHR =2.57 and 2.96, respectively, Table S3).

## Discussion

To the best of our knowledge, this is the first retrospective study that evaluated if the use of statins and/or metformin improved survival in Taiwanese prostate cancer patients who had hyperlipidemia and received radiotherapy. Use of statins or metformin, alone or in combination, did not improve survival time compared with patients who had received neither therapy. However, multivariate analysis found patients without these treatments were associated with higher risk of mortality, although the finding was not statistically significant. Patients who received statins after diagnosis of prostate cancer had a longer average survival time compared with patients who consistently used statins or had statin therapy prior to diagnosis. Similarly, patients who used statins after diagnosis were associated with a reduced risk of mortality compared to those who did not receive or persistently used statins. Patients who received metformin therapy after diagnosis of prostate cancer had a longer average survival time than patients who persistently used the drug or received metformin treatment after diagnosis. However, the use of metformin in patients before diagnosis was significantly

Notes: Multivariate Cox proportional hazards regression model was simultaneously adjusted for age, diabetes mellitus, hypertension, cardiovascular disease, peripheral artery disease, and atherosclerosis. In survival analysis, any cause of deaths was treated as events. Medicine use was defined as using statin and/or metformin at any time during the study period. Patients who did not use either statins or metformin during the study period. Patients who used both statins and metformin at any time during the study period.

Abbreviations: aHR, adjusted hazard ratio; SE, standard error.
associated with a higher risk of mortality compared with patients who did not use metformin. The findings suggested that the use of statins and metformin in Taiwanese prostate cancer patients with hyperlipidemia and radiotherapy may be beneficial, depending upon when the drug is administered.

Our finding, the benefit of statin therapy particularly after diagnosis, is consistent with several large previous studies. With radio-sensitizing properties, statins have antitumor effects which support their beneficial use in prostate cancer.32 Raval et al33 performed a meta-analysis that included 34 observational cohort studies and found a 21% reduction in the risk of biochemical recurrence (BCR) in patients treated with statin and radiation therapy ($P = 0.01$). However, statin use was not associated with BCR in patients who received radical prostatectomy. Raval et al33 also found that statin use was associated with a 22% reduction in the risk of metastasis, and a 24% reduction in risk of both all-cause and prostate cancer-specific mortality. Yu et al34 performed a large cohort study ($N = 11,772$) in men with newly diagnosed, nonmetastatic prostate cancer using a large population-based electronic database from the UK. They found that, during a mean follow-up of 4.4 years, 3,499 deaths occurred, of which 1,791 were from prostate cancer. Similar to the results reported in the current study, post-diagnostic use of statins was associated with a 24% decrease in prostate cancer-specific mortality ($HR = 0.76; 95\% CI = 0.66–0.88$) and a 14% decrease in all-cause mortality ($HR = 0.86; 95\% CI = 0.78–0.95$). Therefore, post-diagnostic statin use among prostate cancer patient who were not previously on a statin may be beneficial.35 However, in contrast to the current study reported here, Yu et al34 found that the association of statin use and decreased risks of prostate cancer and all-cause mortality was more

pronounced in patients who were using statins prior to the
diagnosis (HR =0.55; 95% CI =0.41–0.74; and HR =0.66;
95% CI =0.53–0.81, respectively). Larsen et al36 found that
there was no difference in the effect of post-diagnostic statin
use in Danish prostate cancer patients. Taken together, these
studies suggested that the duration and/or timing of exposure
might be important in statin therapy.35

The importance of statin use following the initiation of
prostate cancer therapy was also investigated in a study by
Harshman et al,37 who retrospectively analyzed 926 men who
had received ADT for biochemical or metastatic recurrence.
They found, after a median follow-up of 5.8 years, that men
using statins had longer median time to disease progression
(27.4 months) than patients not taking statins (17.4 months)
(P<0.001). The benefit of statin therapy was observed both
in patients with and without metastasis. Overall, the findings
from the current study and the prior studies support the use
of statin therapy after the diagnosis of prostate cancer. One
important difference between our study and the previous ones is that our study population only included patients with
hyperlipidemia.

A meta-analysis of 22 trials that assessed statin vs
placebo for the treatment of cardiovascular disease did not
find a significant difference in prostate cancer mortality.38 However, the follow-up time was much shorter in the randomized control trials than that of the observational studies described above. Liu et al,39 in 2017, reported that
the use of statins and metformin were not significantly
associated with treatment outcomes in prostate cancer patients, but lower levels of PSA were observed in patients who
were given statins or metformin. Several studies have
investigated the association of metformin use and mortality
following a prostate cancer diagnosis. A population-based
study by Margel et al40 included 3,837 patients with a
median follow-up of 4.65 years. They found the cumulative
duration of metformin treatment after prostate cancer
diagnosis was associated with a significant decrease in
the risk of prostate cancer-specific and all-cause mortality;
adjusted prostate cancer mortality was 0.76 for each
additional 6 months of metformin use. The association with all-cause mortality was also significant, but declined
to over time from 0.76 in the first 6 months to 0.93 between
24 and 30 months of therapy. The large sample size cohort
studies (a total of 13 cohort studies encompassing 177,490
individuals) in 2017 suggested that metformin treatment
improves survival for patients with prostate cancer.41 The
study of Bensimon et al42 included 935 patients from the
UK, and found no association of metformin use with overall
decreased risk of cancer-specific and all-cause mortality. A
recent meta-analysis of all studies that accounted for the
diagnosis of diabetes found metformin use was associated
with better overall survival and less BCR among prostate
cancer patients.43 Metformin is also the most common
drug used in type II diabetes mellitus. Zingales et al22 sug-
gested that metformin has anticancer activity and could be
potentially used in cancer management. Whereas, Ferro
et al44 reported that diabetic patients with a combination
treatment of metformin and radiation developed increased
acute locoregional toxicity, in comparison with diabetic
patients receiving an alternate diabetes medication and
nondiabetic patients in breast cancer. More investigation
should be conducted to determine the safety in use of
metformin in combination with radiation therapy. Although
our study suggests a benefit of metformin treatment, the
inconsistency across studies indicates additional studies
are necessary to further investigate the role of metformin
in prostate cancer. The current study has several limita-
tions that should be considered while interpreting the
results. Due to the restrictions of the NHIRD database,
information including patient lifestyle, family history,
patient demographics, cancer stage, and clinical labora-
tory data were not available and could not be evaluated.
A previously published study had reported the limitations
cased by the accessibility of their database, which may
introduce measurement error in the definition of the dura-
tion/timing of statin/metformin therapy and in clinical
diagnoses.44 There were also limitations associated with
the statistical analysis. The data we obtained only allowed
for the calculation of overall mortality, so we were unable
to determine prostate cancer-specific mortality or disease-
free survival. The study did not evaluate the length of statin
and/or metformin use on prostate cancer survival. There
were no patients with hyperlipidemia and radiotherapy who
received surgical castration or ADT in NHIRD 2000–2010,
thus the present study could not evaluate these patients.

In conclusion, the present study suggests that statins
and metformin use after the diagnosis of prostate cancer
may increase survival in patients with hyperlipidemia who
received radiotherapy. These findings, along with other stud-
ies, support the use of these medications as adjuvant therapy
for the treatment of prostate cancer. However, more studies
are necessary to further assess their value and also the tim-
ing, length of treatment, and patient population who might
benefit most from their use.

Notes: Continuous variables are shown as mean ± SD; categorical variables are shown as counts (percentages). <sup>1</sup>Significant difference among the groups, P<0.05.

### Table S2 Survival analysis of medicine use for patients with diabetes

<table>
<thead>
<tr>
<th>Medicine use</th>
<th>n of events&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Mean for survival time (years)</th>
<th>SE</th>
<th>Log-rank test, P-value</th>
<th>HR (95% CI)</th>
<th>aHR (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unused</td>
<td>75</td>
<td>7.4</td>
<td>0.2</td>
<td>0.906</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Both</td>
<td>21</td>
<td>7.5</td>
<td>0.4</td>
<td>I</td>
<td>1.17 (0.65–2.08)</td>
<td>1.32 (0.73–3.06)</td>
</tr>
<tr>
<td>Only use statin</td>
<td>15</td>
<td>7.2</td>
<td>0.6</td>
<td>I</td>
<td>1.22 (0.63–2.37)</td>
<td>1.53 (0.76–3.06)</td>
</tr>
<tr>
<td>Only use metformin</td>
<td>14</td>

<td>1.25 (0.64–2.46)</td>
<td>1.43 (0.72–2.83)</td>
</tr>
</tbody>
</table>

Notes: <sup>a</sup>In survival analysis, any cause of death was treated as an event. The Multivariate Cox proportional hazards regression model was simultaneously adjusted for age, hypertension, cardiovascular disease, peripheral artery disease, and atherosclerosis.

Abbreviations: aHR, adjusted hazard ratio; SE, standard error.

### Table S3 Survival analysis of medicine use in only use statin or metformin group for patients with diabetes

</tbody>
</table>

Notes: <sup>a</sup>In survival analysis, any cause of death was treated as an event. <sup>b</sup>Represented a significant difference of average survival time among the groups, log-rank test, P<0.05.

Bold represented a significant factor, P<0.05; the multivariate Cox proportional hazards regression model was simultaneously adjusted for age, hypertension, cardiovascular disease, peripheral artery disease, and atherosclerosis.

Abbreviation: aHR, adjusted hazard ratio; HR, hazard ratio; SE, standard error.
