Introduction and objectives: Short-term extreme increases in desert-derived particulate-matter with aerodynamic diameter below 10 μm (PM₁₀) may affect emergency department (ED) visits due to COPD exacerbations.

Research question: Our aim was to identify the effect of extreme increases in desert-derived PM₁₀ on ED visits for dyspnea and COPD exacerbations and on the related hospital admissions.

Methods: We performed a retrospective analysis of dyspnea-related ED visits and hospital admissions in Heraklion, Crete, during four consecutive storms of desert-derived PM₁₀ that happened during March 2018. We collected data from over 17,000 ED visits and recorded patients with atopic symptoms, COPD exacerbations, and dyspnea, as well as admissions to the departments of pulmonary medicine, internal medicine, and cardiology. PM₁₀ data were collected from a monitoring station in the same geographic area.

Results: Four desert dust storms were recorded during the study period with 238, 203, 1138, and 310 μg/m³ average-daily PM₁₀ and 652, 308, 4262, and 778 μg/m³ hourly mean day-peak PM₁₀, respectively. There was no clinically important increase in total ED visits, total admissions or admissions to the departments of cardiology, pulmonary medicine, or internal medicine, during PM₁₀ peaks. However, during the desert dust storm with daily-average PM₁₀ above 500 μg/m³, there was a striking increase in dyspnea-related ED visits (including COPD exacerbations, 3.6-fold increase), while there was no clinically important increase in non-asthma allergy-related ED visits.

Conclusion: Extreme desert dust storm episodes may cause meaningful increases in ED visits for dyspnea and COPD exacerbations/admissions.

Keywords: Extreme desert dust storm episodes may cause meaningful increases in ED visits for dyspnea and COPD exacerbations/admissions.

Plain language summary

Increased urban particulate-matter with aerodynamic diameter below 10 μm (PM₁₀) may compromise respiratory function in patients with preexisting respiratory diseases. Apart from urban PM₁₀, Southern Europe experiences desert dust PM₁₀ storms due to climatic change. Previous studies have failed to show a significant impact of desert dust storms on emergency department visits for respiratory complaints. We describe the effect of a unique and extreme desert dust storm PM₁₀ storm with daily average PM₁₀>1000 μg/m³ on emergency department overload, focusing on respiratory and especially COPD pathology, in the southernmost region of the European Union, the island of Crete. We conclude that while most desert dust storms do not affect COPD admissions, extreme desert dust storms with a threshold of PM₁₀ above at least 500 μg/m³ may indeed increase ED visits for dyspnea and COPD exacerbations/admissions.
Introduction

Southern European areas frequently experience dust storms caused by certain, well characterized, meteorological conditions that promote transportation of particles from the adjacent Sahara desert. These desert particles consist of fine particulate matter (PM) and are able to penetrate deep in the respiratory system. This is especially true regarding PM with an aerodynamic diameter of less than 10 μm, abbreviated as PM10. PM10 includes desert dust (crustal material), re-suspended dust (crustal and anthropogenic material), sea-salt, anthropogenic inorganic and organic components, and biogenic components.1-3 Although PM10 is expected to compromise respiratory function, especially in patients with preexisting respiratory diseases,4 several previous studies failed to show a statistically significant impact of desert dust storms on emergency department (ED) visits for respiratory complaints.5,6 However, these studies focused mostly on urban areas that are characterized by high levels of human activity derived PM10. Even when adjusting for non-desert PM10, these studies reported relatively small increases in desert-derived PM10 (<100 μg/m3 increases compared to non-desert storm days). Less is known about the short-term effect of the extreme desert dust storms lasting several hours with PM10 levels higher than 200 μg/m3.7

The aim of our study was to report the short-term effect of consecutive extreme increases in desert-originating PM, on ED visits for respiratory symptoms and acute exacerbation of COPD (AECOPD) in the Southmost point of Europe; the island of Crete.

Materials and methods

Study design, setting, and statistical analysis

This is a retrospective analysis of ED visits at the two hospitals located in the city of Heraklion in Crete, the University Hospital of Heraklion (PAGNI, 739 beds) and Venizelion Hospital (440 beds), from March 1st to March 31st, 2018. Both Hospitals cover the Municipality of Heraklion (≥300,000 inhabitants), with a rotating on-call system (every day one of the hospitals is on-call and the other one is on alert). The two hospitals are about 15 km apart and both have fully developed pulmonary medicine departments.

Population

All data regarding the number of ED visits were available for both hospitals, while administrative data from the University Hospital of Heraklion ED were also fully available. The number of patients visiting the ED for allergies (hives, angioedema, or anaphylactic shock), COPD exacerbations, dyspnea unrelated to other well-documented causes (eg, pleural effusion, pneumonia, pulmonary embolism, heart disease, etc.) were recorded. Data regarding the number of admissions to the departments of internal medicine, pulmonary medicine, and cardiology, including admission diagnosis, from both hospitals, were also analyzed. The study design and execution were in compliance with the Declaration of Helsinki. Patient consent to review their medical records was not required by the University Hospital of Heraklion/Venizeleion Hospital Bioethics Committee since only administrative data were collected and patient data anonymity and confidentiality were guaranteed.

Statistical analysis

One-Way ANOVA and Pearson Correlation (PC) with Bonferroni correction for multiple comparisons were performed with IBM SPSS Statistics 21.0 (IBM, Armonk NY, USA).

PM10 data collection

PM10 data were collected and measured by an FH 62 I-R particulate monitor (Thermo TSM Anderson) continuously operating in Heraklion city center. PM10 mass measurements are based on b-attenuation and are conducted in the range 0–10,000 μg/m3 with a resolution of 1 μg/m3. They are found in very good agreement with gravimetric measurements.1

Results

Long-term monitoring of aerosols on Crete is based on PM10 measurements (Figure 1). PM2.5 measurements are not available for the studied period. However, size-segregated PM observations performed over a period of 2 years

Figure 1 Monthly mean of PM10 aerosols in Heraklion, Crete from January to May for the years 2016–2018. Values represent the monthly mean (μg/m3) ± standard deviation.
have shown a good correlation between PM\textsubscript{10} and PM\textsubscript{2.5} measurements with PM\textsubscript{2.5} accounting on average for 60\% of the PM\textsubscript{10} mass.\footnote{\textsuperscript{7}} Dust storms were defined by PM\textsubscript{10} levels above 100 μg/m\textsuperscript{3}, a limit that has been previously used for Asian dust storms.\footnote{\textsuperscript{8,9}} We, therefore, used 24 hrs PM\textsubscript{10} average concentration above 100 μg/m\textsuperscript{3}, to characterize four desert dust storm episodes during the study period. These were between March 3rd and 5th, on March 7th, on March 22nd, and during March 26th-27th with top daily-average (hourly mean day-peak) PM\textsubscript{10} values of 238 (652), 203 (308), 1138 (4262), and 310 (778) μg/m\textsuperscript{3}, respectively. The monthly and the non-peak days PM\textsubscript{10} average were 112 and 24 μg/m\textsuperscript{3}, respectively and were higher compared to previous years (Figure 2A).

Overall, there were 17,239 ED visits in both hospitals. During PM\textsubscript{10} peaks we did not identify clinically important increases in the number of total ED visits, the number of all hospital admissions or the number of admissions to the departments of cardiology, pulmonary medicine, or internal medicine (Figure 2B and C and Table 1).

In the extreme desert dust storm (PM\textsubscript{10}>1000 μg/m\textsuperscript{3}), there was a striking increase (a) in the number of patients presenting to the ED with dyspnea (including COPD exacerbations, 3.6 times vs other days), and (b) in admissions due to COPD exacerbation (4.2 times vs other days) (Figure 2D).

Using Pearson correlation coefficient with Bonferroni correction for multiple comparisons (Table 2) a significant correlation was observed between (a) PM\textsubscript{10} concentrations and ED visits for dyspnea (Pearson Correlation 0.929, \(p<0.00001\)), and (b) PM\textsubscript{10} concentrations and admissions for COPD exacerbations and dyspnea (PC 0.813, \(p=0.0001\) and PC 0.718, \(p<0.001\)) respectively. There was no significant increase in the number of patients visiting the ED for allergies. Regarding the rest of the environmental factors, temperature,

**Figure 2** (A) Particulate matter with aerodynamic diameter below 10 μm (PM\textsubscript{10}) daily average and hourly mean day maximum during March 2018 in the geographic area of Heraklion. (B) Admissions to the departments of internal medicine (Int Med), cardiology (Cardio) and pulmonary (Pulmo) medicine during March 2018. (C) Total emergency department (ED) visits in Heraklion during the study period. (D) ED cases with dyspnea and COPD admissions at the University Hospital of Heraklion during the study period. We did not identify any increases in the studied parameters the days ensuing a desert dust storm.
However, in this study, the percentage of increases and the reported increases of PM were in studies that concentrated on desert dust increases in the range of 36.5 (0.718, 0.041, 0.022, 0.001 p 0.128, 0.313, 0.467, 0.263, 0.178, 0.000 Pearson correlation coef 0.929, 0.464, 0.000 0.040, 0.527, 0.006 546,6 (532,6 187.9 6.6 (4.8 44.8 ⨰ 9.5 (7.2 10.3 (0.0 14.5 (12.7 578 2.8

wind speed, and humidity did not correlate with ED visits or COPD admissions and were not further examined as confounding factors. Wind direction, as expected correlated with clinical events since South wind direction is a prerequisite for the transfer of Sahara dust to the island of Crete.

**Discussion**

The main finding of this study was that only extreme desert dust storms seem to be related to increased ED visits and hospital admissions for dyspnea and COPD. However, even at extreme levels, they do not acutely affect the number of allergic or cardiovascular disease-related events. Although such extreme conditions are rare and currently difficult to predict, emergency physicians and pulmonary medicine specialists in Southern Europe should be aware of the expected high incidence of patients with respiratory compromise, when they occur. Dust storms with lower levels of PM10 do not seem to affect the workload of emergency medicine and pulmonary medicine departments.

Previous studies and meta-analysis on PM effects on health have focused mostly on pollution-related increases of PM10. In studies that concentrated on desert dust storms, the reported outcomes are mostly mortality and hospitalizations, and the reported increases of PM10 were much less compared to the phenomena experienced in Crete on March 2018. A previous study in Athens reported a higher incidence of ED visits for asthma, COPD and respiratory infections by 38%, 57%, and 60%, respectively, for daily PM10 increases in the range of 36.5–78.5 μg/m³. However, in this study, the percentage of increases described are very small compared to the extreme event described in our report, while human-activity related PM10 levels could be a significant confounding factor. Vodonos et al, have also reported a significant correlation between

Table 2 Pearson correlation results for the parameters tested. Significant results after Bonferroni correction of \( p ≤ 0.05/9=0.0056 \) are presented in bold.
desert dust storms and COPD exacerbations in Israel. In accordance with our study, a significant increase in ED respiratory disorders visits, and no effect on all causes hospital admissions, was reported in Sydney, Australia during September 2009 when peak dust storm PM\(_{10}\) levels reached 11,000 μg/m\(^3\). However, in contrast to our results, they reported increases in all-cause ED visits. This difference may be attributed to the higher PM\(_{10}\) levels in the Australian event.

Our research presents, to our best knowledge, the most extreme event of desert dust storm within Europe (for images visit https://www.youtube.com/watch?v=O5gLvUK8FDM). The comparison of the extreme dust storm of March 22nd with the other dust storms during that month, suggests for the first time, that there exists a threshold of daily-average PM\(_{10}\) around (or above) 500 μg/m\(^3\). Above this level, Emergency Services should expect a clinically important increase in the number of patients presenting with respiratory compromise. However, more research is necessary in order to confirm this threshold. A limitation of our study is its short duration. We also did not identify any lag effect between the change of PM10 and the measured effects. A more extended study covering more desert dust storms and a larger population would be more efficient in identifying such effects. However, the desert dust storms sequence during this small period provided us with a unique opportunity to study health effects without major influence from seasonal variations of ED visits and AECOPD due to infections, while the absence of a lag between the massive event on March 22nd and the measured clinical effects suggests that such high levels of desert dust derived PM\(_{10}\) can induce acute (within hours) effects in COPD patients. Another limitation of our study is the use of the administrative data to define admission diagnosis, instead of a per-patient clinical analysis. However, it is unlikely to introduce a significant bias as the same approach was also used for the reference day’s data.

**Conclusion**

Intense desert dust storms with a threshold of PM\(_{10}\) above at least 500 μg/m\(^3\) may cause clinically important increases in ED visits for COPD exacerbations as well as COPD-related admissions. Climatic change may lead to an increased incidence of extreme desert dust storms in Southern Europe. Early identification or prediction of extreme desert dust storms will allow the prompt issue of health warnings for patients with COPD and other preexisting pulmonary diseases to avoid exposure to such irritating conditions and will allow EDs to prepare for climaxes of dyspnea-related cases during these events.
