Introduction: Helicobacter pylori was discovered first in the stomachs of patients with gastritis and ulcers by Marshall and Warren in 1982. This discovery majorly affected many research areas of gastroenterology. Since then, the main aim has been to eradicate this microaerophilic bacterium from the stomachs of infected subjects.

Methods: We studied symptomatic cases by endoscopic surgery and examined the prevalence of cagA–vacA genotypes among the H. pylori isolates. H. pylori isolated from antral biopsies of patients with gastritis and duodenal ulcer were subjected to antimicrobial susceptibility testing and PCR genotyping by using routine bacterial cultures. Clarithromycin-susceptibility profiling was done by the E-test. DNA was extracted using standard manufacturer protocols with minor modifications and cagA and vacA genotyping was done PCR.

Results: In our study, all strains identified as H. pylori in culture (61/81) were confirmed by PCR by amplifying a fragment of the glmM gene. Totally, 61 patients were confirmed to be positive for H. pylori and they were included in the genotyping and antibiotic-susceptibility testing. Thirteen H. pylori strains were determined to be resistant to clarithromycin.

Discussion: Current accumulating data indicate that both clarithromycin-resistant and susceptible isolates of H. pylori need to be screened and tracked in populations.

Keywords: antibiotic susceptibility, cagA, clarithromycin, E-test, Helicobacter pylori, genotypes, PCR, vacA

Introduction
Helicobacter pylori is a well-known bacteria, colonization of which inevitably causes gastroduodenal diseases, including chronic and atrophic gastritis, peptic ulcer disease, mucosa-associated lymphoid tissue lymphoma, and gastric adenocarcinoma.1–3 Because the incidence of digestive diseases associated with H. pylori can vary in different geographical regions, we may postulate that reported cases are dictated by other factors such as bacterial virulence. Virulent strains of H. pylori are generally accepted to cause severe digestive diseases and potentially genetically carry virulence factors.4–6 Furthermore, the discovery that peptic ulcers and acute gastritis can be treated efficiently by antibiotics was an important breakthrough in this century.7,8 Therefore, finding the best effective antibiotic therapy for H. pylori isolates specific to various regions is highly desirable.9 The recent Maastricht guideline was calling for treating all symptomatic H. pylori-infected individuals.10 Broadly defined, three main reasons affect the efficacy of the recommended antibiotics therapies against this persistent bacterium; these include high bacterial load, poor patient compliance, and emergence of antibiotics resistance.11 Among them, emergence of antibiotics
resistance is an undeniable factor. Proton-pump inhibitors (PPI)-clarithromycin containing triple therapy without prior susceptibility testing should be abandoned when the clarithromycin resistance rate in the region is more than 15%. In areas of high (>15%) clarithromycin resistance, bismuth quadruple or non-bismuth quadruple, concomitant (PPI, amoxicillin, clarithromycin and a nitroimidazole) therapies are recommended. In areas of high dual clarithromycin and metronidazole resistance, bismuth quadruple therapy (BQT) is the recommended first-line treatment. In the case of allergic reactions, metronidazole can substitute amoxicillin. Moreover, clarithromycin resistance reportedly decreases the efficacy of therapy by more than 80%. In reality, clarithromycin is a pivotal component in the treatment of H. pylori infection, but the probability of therapeutic failure is relatively high if the resistance rate is more than 15% in the population. In addition, clarithromycin is readily available as a proposed treatment to eradicate H. pylori efficiently in symptomatic individuals. The global resistance rate to clarithromycin has become alarming, and the World Health Organization (WHO) has warned against uncontrolled application of this key antibiotic under clinical settings. The main purpose of our survey is to determine the prevalence of certain virulence factors (cagA and vacA) among clarithromycin-susceptible and clarithromycin-resistant H. pylori strains obtained from symptomatic Iranian patients and to investigate likely significant associations.

Materials And Methods
Sample Collection
This is a cross-sectional study conducted from August 2017 to August 2018. All patients, who were referred for upper gastrointestinal endoscopy at Imam-Hossein Hospital, Tehran, Iran, were enrolled. Three antral biopsy samples were taken from each patient for further analysis. The first biopsy sample was sent for histopathological examination; the second one was used for urease assay (Bahar-Azma, Tehran, Iran); and the last sample was placed in a small 1.5-mL tube containing the thioglycollate broth medium and kept at 4°C for bacterial culturing. The last biopsy samples were processed for bacterial culturing within 4 h of endoscopy. Exclusion criteria included age under 17 or over 80 years, severe cardiovascular diseases, antibiotic therapy against H. pylori 2 months before endoscopy, pregnancy, bleeding problems, history of abdominal surgery a year before endoscopy, alcohol consumption 2 months before biopsy, and consumption of 1) nonsteroidal anti-inflammatory drugs 2) proton-pump inhibitors (PPI), or 3) bismuth a month before enrolment in the study. The study was first presented to, and approved by, the ethics committee of Tarbiat Modares University, Tehran, Iran (IR.TMU.REC. 1397.071), and all patients gave their written informed consent forms to participate before participation. Patients were free to join or leave the study at any time. Additionally, all documents about patients’ endoscopic findings and pathology results were codified and kept confidential.

Bacterial Isolation
All biopsy specimens were first mixed by a vortex for 50 s, and then 150 µl of homogenized suspension was streaked on Brucella agar plates enriched with 10% fetal bovine serum, 8% defibrinated caprine blood, and antibiotics (Selectab, MAST, UK). Plates were incubated at 37°C for 7–12 days under microaerophilic conditions (5% O2, 10% CO2, and 85% N2). After incubation, translucent, grey and small colonies grew and confirmed by biochemical tests (for oxidase, urease, and catalase) to positively identify H. pylori. Moreover, microscopy was used to confirm the bacterial identity by observing typical characteristics, including curved rods and Gram-negative staining. After confirming the identification, typical colonies were harvested and stored at −80°C in brain heart infusion growth medium containing 20% glycerol until further analysis.

Antimicrobial Susceptibility Tests
In this assay, clarithromycin-susceptibility profile of confirmed H. pylori stocks was determined by using the E-test (AB Biodisk, Sweden). First, we have checked that the new plates did not have any contamination and then we placed an E-test strip on the surface of a plate. Following 5–7 days of incubation at microaerophilic conditions at 37°C and with 95% humidity, we rechecked plates to determine zones of inhibited growth. The minimum inhibitory concentration (MIC) for clarithromycin was determined by the E-test following the manufacturer’s instructions but with minor modifications. Strains were considered resistant when MIC was >0.05 µg/mL for clarithromycin. Randomly, 10% of all isolates were selected for double-checking the first reported findings by a second operator.
DNA Extraction And Genotyping

Typical _H. pylori_ colonies were carefully harvested, and DNA was extracted using a commercial kit according to the manufacturer’s instructions (CinnaGen, Tehran, Iran). Extracted DNA was stored at −20°C for further analysis. _glmM_ was used for genetic confirmation of _H. pylori_ besides previous biochemical tests.26 To determine the genotype of the resistant or susceptible strains, we used previously reported primers with minor changes.27 Table 1 shows the primer sets used for PCR; distilled water was used as the negative control replacing the DNA template. To determine the positive or negative results, we subsequently subjected the PCR products (at least 4 μl) to electrophoresis on 1% agarose gels (Sina-clon, Tehran, Iran), and visualized the PCR products by a UV transilluminator (Biometra, Germany).

Statistical Analyses

A chi-square test was used to analyze the possible association between resistance status and particular genotypes ( _cagA_ and _vacA_). All measurements of significance were two-tailed with _P_ < 0.05.

Results

Twenty-eight men and 33 women, with a mean age of 56.8 years (range, 21–73) were included. No statistically significant differences were found between age and gender of patients with _H. pylori_ antibiotic resistance (_P_ < 0.05). In our study, clarithromycin resistance rate was 21% ( _n_ = 13/61). Sixty-one out of 81 patients with duodenal ulcer, gastric ulcer and gastritis were recognized to be infected with _H. pylori_ strains. Indeed, we discard the 20 samples due to lack of enough data from patients, or their disapproval to participate. Nevertheless, positive routine bacterial cultures, classic biochemical tests, and PCR amplification of _glmM_ were used to identify the 61 positive cases. Generally, PCR for _glmM_ detected 61 out of the 61 (100%) confirmed culture samples, indicating reliability and consistency of the two approaches.

Distribution Of _H. pylori cagA_ And _vacA_

In total, 65% ( _n_ = 40/61) of the _H. pylori_ strains were _cagA_-positive. The prevalence of _vacA_ alleles were _s1/m1_ at 40% ( _n_ = 25/61), _s1/m2_ at 21% ( _n_ = 13/61), _s2/m1_ at 14% ( _n_ = 9/61), _s2/m2_ at %22 ( _n_ = 14/61). No statistical association was found between _vacA_ alleles and gastro-duodenal diseases (_P_ > 0.05). The current genotyping on all the 61 _H. pylori_ strains demonstrated that _vacAs1/M1_ (the most virulent genotype based on _vacA_ was the predominant genotype in our study with no significant statistical discrepancy observed among the different disease diagnoses (_P_ > 0.05). Distribution of the combined _cagA_ and _vacA_ genotypes of _H. pylori_ among different diagnoses are summarized in Table 2.

Combination Of Susceptibility Profile With _H. pylori cagA-vacA_ Genotypes

As shown in Table 2, clarithromycin-susceptible _H. pylori_ isolates carried the _cagA+ vacAs1/m1+_ genotype; this association was statistically significant (_P_ < 0.05). The _H. pylori cagA+ vacAs1/m2−_ genotype, as the less virulent strain, did not associate with the resistance phenotype (_P_ > 0.05).

Discussion

Reportedly, _H. pylori_ has colonized 50% of the world population.28 The capacity of _H. pylori_ to cause successful infections is affected by certain elements, which include carrying virulence factors, emergence of antibiotics resistance, and genetic vulnerability in the host.29 Despite identification of _H. pylori_ as the causative agent of various gastritis, designing the best standard therapy to eradicate

this bacterium is still in infancy stages.\(^{30}\) From a biological point of view, the antibiotics-resistant H. pylori strains may have a higher chance to survive and propagate in human gastric microniches; hence, expecting certain virulence types among those pathogenic strains is plausible.\(^{31,32}\) The main rationale for this research was based on this phenomenon that humans may harbor some H. pylori strains that carry virulence elements while they are also resistant to antibiotics. Among the Iranian population, H. pylori clarithromycin resistance is almost as high as 21%, which agrees with other parallel analyses.\(^{33–35}\) However, a fundamental discord exists regarding the positivity of cagA and vacA alleles among the H. pylori strains. Our investigation for the first time has shown that clarithromycin-susceptible H. pylori strains carried the most virulent profile (cagA\(^+\)vacAs\(_1\);\(_1\)). Importantly, some studies, such as that by Alarcón-Millán et al conducted in Mexico, reported no association between any virulence genotypes and clarithromycin-susceptible H. pylori isolates. Our study's limitations include: 1) relatively small number of subjects for antibiotic resistance analysis and 2) short period of time to investigate the clarithromycin susceptibility among H. pylori isolates. Indeed, we had only 1 year to analyze the subjects and assess the two virulent genotypes among both susceptible and resistant H. pylori isolates. Another basic limitation of our study is that we have not checked other virulence factors that may be associated with resistance. However, Alarcón-Millán et al used babA\(_2\) as another possible virulence factor, but they have found no statistically significant association between resistance and cagA genotypes. At last, we were unable to check treatment failure among the patients who utilized clarithromycin within different therapeutic regimens. Indeed, more studies with larger sample sizes could facilitate thorough investigation of the relationship between virulent strains and susceptible H. pylori strains.
Conclusion
We found that some clarithromycin-susceptible *H. pylori* strains carry the virulent genotype, $cagA^vacaSm_i^j$, and this can exacerbate the management of this persistent microorganism. Cumulative data indicate that both clarithromycin-resistant and clarithromycin-susceptible isolates of *H. pylori* need to be screened and tracked in regional populations. Thus, even the clarithromycin-susceptible *H. pylori* isolates should not be underestimated in the clinics.

Ethics
Our study was conducted in accordance with the Declaration of Helsinki.

*Infection and Drug Resistance* is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of antibiotic resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
