Detection of Novel Gene Mutations Associated with Pyrazinamide Resistance in Multidrug-Resistant Mycobacterium tuberculosis Clinical Isolates in Southern China

Objective: Pyrazinamide (PZA) is a cornerstone of modern tuberculosis regimens. This study aimed to investigate the performance of genotypic testing of pncA upstream region, rpsA, panD, Rv2783c, and clpC1 genes to add insights for more accurate molecular diagnosis of PZA-resistant (R) Mycobacterium tuberculosis.

Methods: Drug susceptibility testing, sequencing analysis of PZA-related genes including the entire operon of pncA (Rv2044c-pncA-Rv2042c) and PZase assay were performed for 448 M. tuberculosis clinical isolates.

Results: Our data showed that among 448 M. tuberculosis clinical isolates, 113 were MDR, 195 pre-XDR and 70 XDR TB, while the remaining 70 strains had other combinations of drug-resistance. A total of 60.04% (269/448) M. tuberculosis clinical isolates were resistant to PZA, of which 78/113 were MDR, 119/195 pre-XDR and 29/70 XDR TB strains. PZA R isolates have predominance (83.3%) of Beijing genotype. Genotypic characterization of Rv2044c-pncA-Rv2042c revealed novel nonsynonymous mutations in Rv2044c with negative PZase activity which led to confer PZA R. Compared with phenotypic data, 84.38% (227/269) PZA R strains with mutations in pncA upstream region exhibited 83.64% sensitivity but the combined evaluation of the mutations in rpsA 2.60% (7/269), panD 1.48% (4/269), Rv2783c 1.11% (3/269) and Rv2044c 0.74% (2/269) increased the sensitivity to 89.59%. Fifty-seven novel mutations were identified in this study. Interestingly, a frameshift deletion (C—114del) in upstream of pncA nullified the effect of A—11G mutation and induced positive PZase activity, divergent from five PZase negative A—11G PZA R mutants. Twenty-six PZA R strains having wild-type-sequence genes with positive or negative PZase suggest the existence of unknown resistance mechanisms.

Conclusion: Our study revealed that PZA R rate in MDR and pre-XDR TB was markedly higher in southern China. The concomitant evaluation of pncA upstream region exhibited 83.64% sensitivity but the combined evaluation of the mutations in rpsA 2.60% (7/269), panD 1.48% (4/269), Rv2783c 1.11% (3/269) and Rv2044c 0.74% (2/269) increased the sensitivity to 89.59%. Fifty-seven novel mutations/indels in this study may play a vital role as diagnostic markers. The upstream region of pncA and PZase regulation are valuable to explore the unknown mechanism of PZA-resistance.

Keywords: tuberculosis, pyrazinamidase, drug resistance, molecular diagnosis, novel mutations, frameshift deletion

Introduction

Pyrazinamide (PZA), an analog of nicotinamide, is a key component of current and new anti-tuberculosis (TB) regimens for treatment of both drug-susceptible and multidrug-resistant (MDR) TB, because it plays a critical role in shortening the TB...
therapy from 9 to 12 months to 6 months. PZA has a unique sterilizing activity against *Mycobacterium tuberculosis* persisters that are not killed effectively by other anti-TB drugs, but its mechanism of action is complex and not well understood yet.²

PZA is a prodrug that is converted to its active form, pyrazinoic acid (POA), by an enzyme, pyrazinamidase (PZase), encoded by *pncA* gene.³ Averagely, 70% to 90% of PZA resistance (R) incidences are due to mutations in the *pncA* gene.⁴,⁵ In recent studies, RpsA which encodes the ribosomal protein S1, involved in translation and translation, has been reported as a target of PZA.⁶ The mutations in *rpsA* seem to have a minor role in PZA³ in the clinical isolates having no mutation in *pncA* gene.³,⁷ Besides, another gene *panD* encoding aspartate decarboxylase involved in beta-alanine and pantothenate synthesis was recently identified, whose mutations were also associated with PZA³ in *M. tuberculosis* strains lacking *pncA* and *rpsA* mutations.⁸

In our recent study, we discovered Rv2783 as a new potential target of POA in *M. tuberculosis*.⁹ Rv2783, a bifunctional enzyme which was proved to be able to synthesize and hydrolyze (p)ppGpp and to synthesize and hydrolyze ssDNA and ssRNA without any template.⁹ In addition to the above genes, ClpC1 was reported as another new target of PZA which acts as an unfolding enzyme in concert with the proteases ClpP1 and ClpP2 of the caseinolytic protease complex but the mutations in the coding region of ClpC1 were associated with PZA³,¹⁰

The Wayne assay exhibits the association between PZase activity and genetic mutations in PZA-associated genes. Mutations in *pncA* gene are considered to be responsible for the failure of key-lock recognition mechanism between the enzyme and its substrate. Similarly, when mutation occurs in the upstream flanking region (UFR) of *pncA*, the RNA polymerase may not be able to transcribe it. Thus, there is no PZase activity and PZA cannot be converted into POA.¹¹ *pncA* (Rv2043c) is co-transcribed as a polycistron (Rv2044c-*pncA*-Rv2042c) with its upstream gene Rv2044c and downstream gene Rv2042c.¹² However, apart from frequently observed mutations at position -11 in the putative regulatory region of *pncA*, no reports showed yet that mutations in the instant upstream gene of wild-type (wt) *pncA* may develop PZA³ in *M. tuberculosis*.

The prior studies described the correlation between PZA³ and *pncA* mutations. Whereas no study has been conducted so far for simultaneous characterization of the mutations in *pncA*³ UFR, *rpsA*, *panD*, Rv2783c, and clpC1 for the detection of PZA³ in MDR, pre-XDR (MDR with additional resistant to fluoroquinolone or a second-line injectable drug, e.g. kanamycin, amikacin) and XDR (MDR in addition with resistant to both fluoroquinolones and second-line injectable drugs) *M. tuberculosis* clinical isolates. The currently available phenotypic PZA susceptibility testing methods are complicated and deceptive because of frequent false-resistance and false-susceptible results.¹³ Genotypic characterization of PZA-related genes has been endorsed to overcome the shortcomings of phenotypic susceptibility testing methods.¹⁴

In this study, to evaluate the performance of genotypic testing method of PZA-associated genes for detecting PZA³ strains, we performed the phenotypic and genotypic characterization of 448 *M. tuberculosis* clinical isolates from southern China. Considering the observation that UFR of *pncA* has an indispensable role in PZase regulation as well as PZA³,¹¹,¹² we have additionally evaluated the complete operon of *pncA* (Rv2044c-*pncA*-Rv2042c) to identify the possible role of surrounding genes of *pncA* in PZA³ *M. tuberculosis*.

## Materials and Methods

### Ethical Approval

The current study was approved by the Ethics Committee of Guangzhou Chest Hospital (GZXXK-2016-015) in accordance with the WHO-approved guidelines.

### Collection of *M. tuberculosis* Clinical Isolates

In this study, 448 drug-resistant *M. tuberculosis* clinical isolates (resistant ≥ one anti-TB drug) were collected during the period from December 2016 to November 2018 from TB patients at Guangzhou Chest Hospital, the biggest TB-specialized hospital in southern China. Ziehl–Neelsen staining and commercial MPB64 monoclonal antibody assay (GENESIS, Hangzhou, China) were performed to confirm the *M. tuberculosis* species.¹⁵

### Drug Susceptibility Testing

Drug susceptibility testing (DST) of 448 *M. tuberculosis* isolates was first assessed by Mycobacterial Growth Indicator Tubes (MGIT) 960 (Becton Dickinson, Franklin Lakes, NJ, USA). The critical concentrations (µg/mL) for DST were consistent with WHO recommendations; isoniazid (INH; 0.1), rifampicin (RIF; 1.0), ethambutol (EMB; 5.0), PZA (100), streptomycin (STR; 1.0), levofloxacin (LVX; 1.0), moxifloxacin (MXF; 0.25) and amikacin (AMK; 1.0).¹⁶ In order to measure the extent of
phenotypic PZA\textsuperscript{R} by the gold standard MGIT 960 system, the higher concentrations of PZA (300 and 900 \(\mu\)g/mL) were tested particularly for those PZA\textsuperscript{R} (100 \(\mu\)g/mL) strains which showed inconsistent phenotypic and genotypic results. The DST results were also verified via indirect proportion method on Löwenstein–Jensen medium using the recommended concentrations (\(\mu\)g/mL); INH (0.2), RIF (40.0), EMB (2.0), STR (4.0), LVX (2.0), MXF (1.0) and AMK (30.0).\textsuperscript{16} The growth on a control medium (drug-free medium) was compared with the growth on drug-containing medium and the resistance was determined when 1\% or more growth was noticed at the critical concentration of drug in the medium.\textsuperscript{16}

**PZase Activity Assay**

PZase activity assay was performed with some modifications in a Wayne test\textsuperscript{8} to determine the PZase regulation. Briefly, 3 to 4 pure and freshly grown \textit{M. tuberculosis} colonies on LJ medium were scraped off and transferred into 1 mL Middlebrook 7H9 medium supplemented with albumin-dextrose-catalase (ADC) containing PZA (100 and 200 \(\mu\)g/mL) in 1.5 mL Eppendorf tubes. The colonies were incubated at 37\(^\circ\)C in a shaker for 3, 5, and 7 days. Later, 15 \(\mu\)L of 2\% Fe\textsuperscript{2+} was added into the bacterial cells and incubated at 4\(^\circ\)C for 2–4 hrs for color appearance. \textit{M. tuberculosis} H37Rv\textsuperscript{wt} (pyrazinamide-susceptible; PZA\textsuperscript{S}) and \textit{M. bovis} Bacillus Calmette-Guérin (BCG) Tice (PZA\textsuperscript{R}) were used as positive and negative controls, respectively.

**PZA-Associated Genes Amplification and Sequencing**

Genomic DNA was extracted from freshly grown \textit{M. tuberculosis} cultures using MagMAX Total Nucleic Acid Isolation Kit (Ambion, Life Technologies, NY, USA) according to the manufacturer’s instructions. All PZA-associated genes (\textit{pncA}, \textit{rpsA}, \textit{panD}, \textit{Rv2783c} and \textit{clpC1}) including their 5\’ upstream (\(\leq - 200\) bp) to 3\’ downstream (\(\leq + 200\) bp) regions were amplified in all \textit{M. tuberculosis} isolates using the newly designed primers in this study (Table 1). The complete operon of \textit{pncA} (\textit{Rv2044c-pncA-Rv2042c}) was additionally analyzed in PZA\textsuperscript{R} strains. PCR products were examined on agarose gels, purified by PCR purification kit (Qiagen, Hilden, Germany) and sequenced at the BGI (Guangzhou, China). The DNA sequences were compared with the reference sequence of \textit{M. tuberculosis} H37Rv (Accession number: NC_000962.3) using the software BioEdit version 7.2.6.1.

**Detection of Beijing and Non-Beijing Genotypes**

Multiplex PCR method was used to distinguish Beijing and non-Beijing genotypes as previously described\textsuperscript{17} that region spanning genes \textit{Rv2816} to \textit{Rv2819} including part of \textit{Rv2820} is missing in Beijing genotype of \textit{M. tuberculosis} strain. A set of primers BJ-F: 5\’-ACCGAGCTGATCAAACCGG-3\’ and BJ-R: 5\’-ATGGCACGCGACCTGAATGAACC-3\’ amplified the 239 bp PCR product containing region-specific part of \textit{Rv2819} and part of \textit{Rv2820} in Beijing genotypes. Whereas another pair of primers NBJ-F: 5\’-GATCGCTTTTCTCAGTGCA-3\’ and NBJ-R: 5\’-CGAAGTGATACGTGGAG-3’ is used to detect non-Beijing genotypes by amplification of 539 bp PCR fragment from \textit{Rv2819} gene. The PCR products were observed on agarose gels.

**Statistical Analysis**

Phenotypic PZA susceptibility testing and the PZase assay were used as references. Associations among multiple aspects between PZA\textsuperscript{S} and PZA\textsuperscript{R} strains were analyzed with Pearson Chi-square test. A paired Chi-square test was used via MEDCALC\textsuperscript{®} statistical software (https://www.medcalc.org/calc/diagnostic_test.php) to measure the sensitivity, specificity, odds ratio (OR), 95\% confidence interval (CI) and accuracy of PZA genotypic susceptibility testing method. \textit{P}-value of <0.05 was considered statistically significant.

**Results**

**Demographic Characteristics**

Of the 448 \textit{M. tuberculosis} isolates, 71.20\% (319/448) were from male patients and 28.79\% (129/448) were from female patients. Age range was 15 to 89 years with a mean age of \(\sim 41.2\) years. Majority of TB patients 62.5\% (280/448) examined in this study were previously treated cases and 69.86\% (313/448) TB patients enrolled in the current study was migrant population.

**Drug Susceptibility Profiles of \textit{M. tuberculosis} Clinical Isolates**

Among the 448 \textit{M. tuberculosis} clinical isolates, 113 were identified as MDR, 195 pre-XDR and 70 XDR TB, while the remaining 70 strains had a random pattern of drug resistance. Total 60.04\% (269/448) \textit{M. tuberculosis} clinical isolates assessed by gold standard MGIT 960 system were PZA\textsuperscript{R} in this study which were categorized as 69.02\% (78/113) MDR,
61.02% (119/195) pre-XDR and 41.42% (29/70) XDR *M. tuberculosis* which collectively covered 59.8% (226/378) of the total (M/pre-X/X-DR) TB strains (Table 2).

**Notes:** *Indicates significantly higher rate than XDR TB in PZA R isolates while in PZA S isolates significantly higher rate than MDR TB measured by Chi-square test. # shows the number of drug-resistant strains with several distinct combinations of resistance against tested anti-TB drugs. MDR TB: *M. tuberculosis* strain resistant to at least INH and RIF. Pre-XDR TB: MDR strain additionally resistant to either a fluoroquinolone (FQ) or a second-line injectable drug but not both at the same time. XDR TB: MDR TB along with resistant to any fluoroquinolone (FQ) and at least one injectable second-line drug (e.g. amikacin, kanamycin, etc.) simultaneously.

Genotypes of PZA-Resistant Isolates

Genotyping by multiplex PCR-based method demonstrated that overall 80.58% (361/448) belonged to Beijing genotype and the other 19.42% (87/448) to non-Beijing genotype in total studied isolates. The distribution of these total Beijing and non-Beijing genotypes in PZA R and PZA S strains is given in Table 3. PZA R isolates predominantly (83.3%; 224/269) belonged to the Beijing genotype, whereas, 16.7% (45/269) PZA R isolates were from non-Beijing genotype family of *M. tuberculosis* strains.

### Table 3 Association Between Mutations in pncA + UFR and PZase Enzyme Activity

Among the 84.38% (227/269) PZA R strains detected with pncA + UFR mutations (Table S1), 23.78% (54/227) exhibited insertions/deletions (indels) in pncA coding region, 5.72% (13/227) had stop codon mutations, 59.03% (134/227) carried single nonsynonymous mutation, 0.44% (1/227) had multiple mutations, 0.88% (2/227) showed synonymous mutation and 5.28% (12/227) had mutations both in
pncA and its UFR. The amino acid substitutions/indels in pncA were scattered over the gene including the nonsynonymous mutations near the active site or metal-binding site. However, 4.84% (11/227) PZA R strains had mutations/indels only in the UFR of pncA wt with frequently existed substitutions at −11 position. The PZase assay revealed that 3.96% (9/227) PZA R strains had positive or weakly positive PZase activity, though they had indels or synonymous mutation in pncA gene or its UFR while the remaining 96.03% (218/227) were PZase negative (Table 4).

In addition, among the substitutions located at −11 position, five A−11G PZA R mutants were detected with negative PZase activity but a very interesting phenomenon was identified in this study that one A−11G PZA R mutant having a deletion of C nucleotide at position −114 in the UFR of pncA showed positive PZase activity, which suggests that C−114del possibly altered the effect of A−11G mutation and induced the normal regulation of PZase (PZase positive) in this PZA R strain. On the whole, 21.14% (48/227) new nonsynonymous mutations/indels were found in pncA and its UFR in this study.

Mutations in rpsA, panD, Rv2783c and clpC1

In this study, 2.60% (7/269) PZA R strains carried nonsynonymous mutations (Thr29Met; Gln162Arg; Ala412Val) in RpsA (Table S2). Two of them (Gln162Arg, Ala412Val) were identified first time in this study. A synonymous mutation (Arg212Arg) in RpsA was frequently observed in both PZA S and PZA R strains. Further, we found 1.48% (4/269) PZA R strains with Leu132Pro and Pro134Ser mutations in the C-terminus of PanD which possibly alter the protein structure and cause resistance. The mutation Leu132Pro is recognized as a novel mutation in PanD. It is interesting to note that, a new nonsynonymous mutation (Ser149Pro) was detected in Rv2783c of 1.11% (3/269) PZA R strains, whereas no mutation occurred in clpC1 gene or its promoter region.

Characterization of Rv2044c-pncA-Rv2042c in pncA wt PZA R Strains

Most importantly, 10.40% (28/269) PZA R strains were found without mutation in the above-sequenced genes. The phenotypic resistance of these strains were reconfirmed by using higher concentration (300 and 900 μg/mL) of PZA and the genotypic assessment of entire operon of pncA (Rv2044c-pncA-Rv2042c) was performed. It is worth noting that among the total PZA R strains, 0.74% (2/269) PZA R strains were identified with nonsynonymous mutations (Tyr70His, Ile71Asn, Trp80Gly) and (Trp80Leu, Ala82Asp) in Rv2044 (the instant upstream gene of pncA) and produced negative PZase activity (Figure 1). Interestingly, 9.7% (26/269) of the

Note: PZA S strains (179/448) were observed with positive PZase activity.

Abbreviations: PZase, pyrazinamidase; UFR, upstream flanking region of pncA.
total PZA\textsuperscript{R} strains were discovered without any mutation in all known PZA-associated genes. Among these 26 PZA\textsuperscript{R} strains, 34.61\% (9/26) produced negative PZase activity and 65.38\% (17/26) PZA\textsuperscript{R} strains had positive PZase activity (Table 4) in PZase assay. The genotypic reassessment also confirmed no mutation in all sequenced genes in these PZA\textsuperscript{R} strains. Overall, 23.45\% (57/243) novel mutations/indels were identified in \textit{pncA}+UFR, \textit{rpsA}, \textit{panD}, Rv2783c and Rv2044c genes among the total 90.3\% (243/269) genetic mutations in PZA\textsuperscript{R} strains.

**DNA Sequencing Analysis of Phenotypic PZA\textsuperscript{S} Strains**

Of the total 39.95\% (179/448) PZA\textsuperscript{S} strains, 1.67\% (3/179) harbored synonymous mutations, 0.55\% (1/179) insertion and 3.35\% (6/179) were noticed with single nonsynonymous mutations only in \textit{pncA} of phenotypic PZA\textsuperscript{S} strains with positive PZase activity (Table S3), while 94.41\% (169/179) PZA\textsuperscript{S} strains were found with wild-type \textit{pncA} and other sequenced genes along with positive PZase activity.

**Prediction of PZA\textsuperscript{R} Isolates Based on DNA Sequencing**

To examine the performance of DNA sequencing method for detection of PZA\textsuperscript{R} isolates, the genotypic and phenotypic results of 448 \textit{M. tuberculosis} isolates were compared. Using the phenotypic results as a reference, the sequencing method exhibited 75.09\% sensitivity and 96.09\% specificity for the mutations only in the \textit{pncA} coding region, but the genotypic characterization of \textit{pncA} accompanied by its UFR improved the sensitivity to 83.64\% while specificity remained unchanged. The individual sequencing of \textit{rpsA}, \textit{panD}, Rv2783c, and Rv2044c showed low sensitivities, indicating minor diagnostic role of their own. However, the combined evaluation of mutations in \textit{pncA} + UFR, \textit{rpsA}, \textit{panD}, Rv2783c, and Rv2044c genes increased the sensitivity from 75.09\% to 89.59\% with 92.19\% accuracy and 96.09\% specificity (Table 5).

**Evaluation of Association of PZase Assay with MGIT 960 and DNA Sequencing**

Phenotypically PZA\textsuperscript{R} \textit{M. tuberculosis} strains assessed by MGIT 960 usually show PZase negative activity (PZase -) because of mutation in \textit{pncA} gene which disrupts the PZase regulation. Whereas PZA\textsuperscript{R} \textit{M. tuberculosis} strains without \textit{pncA} mutation possess positive PZase activity (PZase +). The correlation between PZase activity assay and MGIT 960 showed the sensitivity (85.13\%, [95\% CI: 80.31–89.16]) and specificity (100\%, [95\% CI: 97.96–100]) with the accuracy of (91.07\%, [95\% CI: 88.04–93.54]) due to the high number (269/448) of PZA\textsuperscript{R} strains. Besides, the
association between genotypic testing and PZase assay exhibited the sensitivity (81.78%, [95% CI: 76.64–86.21]) and specificity (96.09%, [95% CI: 92.11–98.41]) with the accuracy of (87.50%, [95% CI: 84.08–90.42]) because of high incidence of resistance-conferring \( pncA^+ \) UFR mutations.

**Discussion**

This study shows the prevalence rates of PZA\(^R \) in MDR (69%) and pre-XDR (61%) TB in southern China were higher than the MDR TB observed in South Africa (52.1%), Japan (52.8%) and Thailand (49.0%)\(^{19,20} \), but in line with another recently published study.\(^{21} \) Beijing genotype was the most dominant genotype 80.58% (361/448) observed in southern China, similar to the studies from Beijing\(^{22} \) and Zhejiang\(^{23} \). PZA has an imperative role in current and new anti-TB regimens including the promising Pa-824 + Moxifloxacin + PZA, bedaquiline + PZA\(^R \) and clofazimine + PZA containing regimens.\(^{24} \) Our study comprehensively investigates the genetic mutations in PZA-related genes (\( pncA, rpsA, panD, Rv2783c, \) and \( clpC1 \)) in addition with the complete operon of \( pncA \) (\( Rv2044c-pncA-Rv2042c \)) in a wide-range of \( M. \) *tuberculosis* clinical isolates.

The detection of 84.38% (227/269) \( pncA + \) UFR mutations in PZA\(^R \) strains in this study was markedly higher than previous reports from Thailand (75.0%)\(^{19} \), Brazil (45.7%)\(^{26} \) and other parts of China (78.0%).\(^{23} \) Though mutations in \( pncA \) scattered all over the gene and its UFR but a certain frequency of \( pncA \) mutations has been observed at amino acid residues 3 to 12, 46 to 62, 67 to 85, 94 to 103, and 132 to 142 which were the areas close to the PZase active sites (Asp8, Lys96, and Val139) or metal ion binding sites (Asp49, His51, His57, and His71).\(^{23} \) Our findings are coherent with the previous studies.\(^{20,23} \) So, the absence of “hot spot” regions make it quite challenging to develop rapid diagnostic assays for detection of PZA\(^R \) isolates based on indel or nonsynonymous mutations in the \( pncA \).\(^{13,27} \)

The \( rpsA \) gene has been ambiguously discussed in the literature as both supportive and opposing studies have been
published regarding the role of RpsA in PZAR strains.\textsuperscript{12,28,29} However, two novel mutations (Gln162Arg; Ala412Val) are identified in RpsA of PZAR isolates in this study. Moreover, mutations in \textit{panD} have also been associated with PZAR in clinical isolates lacking mutations in \textit{pncA} and \textit{rpsA}.\textsuperscript{8} The C-terminus of PanD protein spanning amino acid residues 114–139, where all the PanD mutations are usually mapped may affect the binding of the active form of PZA (POA) without abolishing PanD’s enzymatic activity.\textsuperscript{30} We discerned (Leu132Pro and Pro134Ser) mutations in the C-terminus of PanD in PZAR isolates. Leu132Pro is recognized as a novel mutation in our study. Though another study reported (Leu132Arg) and (Leu136Arg) mutations in PanD\textsuperscript{31} but these mutations were different from our findings regarding the amino acid substitutions.

Furthermore, Rv2783 plays an important role in the general homeostasis of (p)ppGpp during dormancy; however, POA inhibits its function in wild-type strain, but the Asp67Asn mutation helps in circumvention of POA \textsuperscript{eral homeostasis of (p)ppGpp during dormancy; however, POA inhibits its function in wild-type strain, but the Asp67Asn mutation helps in circumvention of POA.} \textsuperscript{9} In this study, we identified three PZAR strains with positive PZase activities bearing one novel nonsynonymous mutation (Ser149Pro) in Rv2783, which supports that Rv2783 is a potential target of POA.\textsuperscript{9} Likewise, \textit{clpC1} (Rv3596c) involved in protein degradation by assembling a protease complex through ClpP1 and ClpP2, was proposed to be a new target of PZA and the mutations (Gly99Asp, Lys209Glu) in N-terminal and D1 domain have been interrelated with PZAR strains.\textsuperscript{10,27} However, there was no any mutation in \textit{clpC1orf} of \textit{M. tuberculosis} clinical isolates in this study. This degradative protease is essential for the viability, survival, and virulence of \textit{M. tuberculosis}. Therefore, the \textit{M. tuberculosis} strains containing mutations in \textit{ClpC1} may not be able to survive well in the host, so it is hard to get such mutants in clinical isolates.\textsuperscript{7,32}

On the other hand, 10.40% (28/269) PZAR strains were observed without any mutation in \textit{pncA}, \textit{rpsA}, \textit{panD}, \textit{Rv2783c}, and \textit{clpC1} genes. However, to determine the significant role of UFR of \textit{pncA} and its surrounding genes in PZase regulation,\textsuperscript{11,12} we sequenced the complete operon of \textit{pncA} (Rv2044c-\textit{pncA}-Rv2042c) in these PZAR strains. Notably, two of these PZAR strains were detected with novel missense mutations “Tyr70His, Ile71Asn, Thr80Gly” and “Trp80Leu, Ala82Asp” in Rv2044 first time in this study. Interestingly, these strains exhibited the negative PZase activity in PZase assay which was likely to be the effect of these mutations. However, in-depth impact of these mutations on PZase regulation needs to be investigated in imminent studies. This observation is also supported by another recent study where an important frameshift deletion was identified in \textit{Rv2044c} that interrupted the stop codon and led to its fusion with \textit{pncA} which engendered the addition of a novel domain of unknown function (DUF2784) to the PZase enzyme.\textsuperscript{33} Overall, 23.45% (57/243) novel mutations/indels were detected in PZAR strains in our study.

PZAR strains with missense mutations/insertion in \textit{pncA} were reconfirmed by phenotypic and genotypic assays. The mutation (T92G→Ile31Ser) has been previously described in both PZAS and PZAR isolates with similar PZase characteristics,\textsuperscript{19} whereas Thr47Ala was also reported without its involvement in PZAR.\textsuperscript{34} The mutations in susceptible strains were unable to encounter the threshold of resistance.\textsuperscript{13} No nonsynonymous mutations/indels were identified in the genes other than \textit{pncA} in PZAS strains.

Compared to the phenotypic data, the sensitivity for detecting PZAR by DNA sequencing of \textit{pncA} gene along with its UFR was 83.64% with 96.09% specificity which was consistent with the data from South Korea (84.6%)\textsuperscript{15} and the United States (84.6%),\textsuperscript{36} only a little higher than the studies from northern China (77.97%),\textsuperscript{23} Thailand (75%)\textsuperscript{19} and Sierra Leone (70%)\textsuperscript{37} but lower than the findings from Netherlands (96.8%).\textsuperscript{38} Moreover, the combined assessment of mutations in \textit{pncA} + UFR, \textit{rpsA}, \textit{panD}, \textit{Rv2783c}, and \textit{Rv2044c} increased the sensitivity up to 89.59% which strengthens their share for detection of PZAR \textit{M. tuberculosis} clinical isolates.

In agreement with the several studies, the current study demonstrated that mutations in \textit{pncA} gene turns the regular enzyme activity into PZase negative; however, nine PZAR strains with synonymous mutations/indels in the \textit{pncA} or its UFR in our study retained the positive/weakly positive PZase activity and may have the involvement of enigmatic mechanism(s) of resistance against PZA. The PZase activity assay in association with MGIT 960 susceptibility testing showed 85.13% sensitivity. In the same way, the correlation between PZase assay and genotypic testing presented the sensitivity of 81.78% and 96.09% specificity in our study, which is significantly higher than previously published study (68.6%) and (45.7%)\textsuperscript{39} but slightly lower than another report 88.2% and 88.8%,\textsuperscript{39} respectively. Similar to previous reports, the mutations in \textit{rpsA}, \textit{panD} and \textit{Rv2783c} were not found to be associated with loss of PZase activity in PZAR strains lacking \textit{pncA} mutation.\textsuperscript{6,8,9,26,30}
In contrast, the substitution at position −11 of pncA usually possess negative PZase activity in PZA$^R$ strains.\textsuperscript{40} While we identified one A−11G PZA$^R$ mutant having a deletion of C nucleotide at position −114 in the UFR of pncA showed PZase positive, that was completely divergent from five other PZase positive A−11G PZA$^R$ mutants, which proposes that C−114del might turn the impact of A−11G mutation and produced positive PZase activity in this PZA$^R$ strain. This needs to be further studied in the forthcoming studies. Moreover, the consistent results of phenotypic and genotypic reassessment of 34.61% (9/26) PZase negative and 65.38% (17/26) PZase positive PZA$^R$ strains without any known mutation in all reported PZA$^R$-related genes direct their linkage with cryptic resistance mechanisms of PZA in \textit{M. tuberculosis}.

**Conclusion**

In conclusion, to the best of our knowledge, this is the first study, covering the combined phenotypic and genotypic characterization of all PZA$^R$-associated genes in a wide range of \textit{M. tuberculosis} clinical isolates. PZA$^R$ rate among MDR (69%) and pre-XDR TB (61%) was considerably higher in southern China. Though \textit{pncA} played a major role (>80%) in PZA$^R$ but the simultaneous evaluation of other PZA$^R$ related genes increased the sensitivity to ~90%. Considering the difficulty of phenotypic susceptibility testing method, our data suggest that concomitant detection of mutations in \textit{pncA}$^+$ UFR, \textit{rpsA}, \textit{pnd}, \textit{Rv2783c}, and \textit{Rv2044c} is more dependable. The addition of 57 novel mutations/indels from our study in drug-resistance TB mutation database may increase the reliability of molecular diagnosis. In addition, the substitutions at positions −11 and −12 in \textit{pncA} UFR caused negative PZase activity but deletion of C nucleotide at −114 altered the effect of A−11G mutation and established the normal regulation of PZase, though the strain was still resistant to PZA. In addition, the loss of PZase activity due to newly identified mutations in \textit{Rv2044} led to confer PZA$^R$ in \textit{M. tuberculosis}. Lastly, the nine PZase positive PZA$^R$ mutants bearing \textit{pncA} synonymous mutations/indels and 26 PZA$^R$ strains lacking any mutation in all reported PZA$^R$-related genes with discordant PZase activities implicate the existence of unknown resistance mechanisms that need to be uncovered.
