Abstract: Anti-γ-aminobutyric acid B receptor (anti-GABA_BR) encephalitis is a rare type of autoimmune encephalitis (AE). Although it responds well to immunomodulating therapy and has favorable prognosis, anti-GABA_BR AE has often been misdiagnosed as infectious encephalitis. Herein, we present a case of a 59-year-old female with anti-GABA_BR AE associated with small cell lung cancer (SCLC) that was once misdiagnosed as infectious encephalitis. Our findings increase the awareness that patients presenting with a clinical trial of cognitive impairment, seizures and SCLC may harbor AE. Our case also highlights the importance of anti-SOX1 antibody in the detection of SCLC.

Keywords: autoimmune encephalitis, anti-GABA_B receptor, small cell lung cancer

Introduction

Anti-γ-aminobutyric acid B receptor (anti-GABA_BR) encephalitis is a rare type of autoimmune encephalitis (AE) associated with anti-neuronal cell surface antibodies and accounts for approximately 5% of patients with autoimmune synaptic encephalitis.¹ The most characteristic presentations of this disorder include seizures, cognitive impairment, confusion, and personality changes.² Nearly 50% of patients with this condition harbor an underlying tumor, particularly a small cell lung cancer (SCLC) or pulmonary neuroendocrine tumor.³ Immunotherapy often results in good outcomes and relapse is uncommon.⁴ The SOX1 protein is a part of SRY-like high mobility group superfamily of developmental transcription factors and anti-SOX1 antibody was described as immunobiomarker of SCLC.⁵ Early recognition of anti-SOX1 antibody, identified underlying neoplasm, and prompt initiation of immunotherapy are essential to achieve a better outcome.

As far as we know, only a few cases have been reported to date and its clinical manifestations and treatment have not been investigated systematically. Herein, we reported a 59-year-old woman presenting as rapidly progressive cognitive impairment and seizures diagnosed as AE with anti-SOX1 and anti-GABA_BR antibody and finally confirmed by biopsy as SCLC.

Case Report

A 59-year-old woman presented at our hospital with memory deficit for 12 days and recurrent convulsions for 8 days. She usually could not remember what she had eaten an hour ago and always complained why her brother did not come to visit her.

In fact, her brother had been dead for many years. Four days later, she experienced three convulsions, which lasted about 10 mins every time, manifesting as body stiffness, rolling eyes, foaming at the mouth, urinary incontinence, and consciousness disturbance. She was previously healthy and had no family history of psychiatric disorders. Blood routine examination showed elevated leukocyte count ($10.03 \times 10^9/L$, normal range $4-10^9/L$). Considering the possibility of infectious encephalitis, she was treated with ganciclovir 0.25g b.i.d, piperacillin sodium and tazobactam sodium 0.45g t.i.d for 5days, and phenobarbital in the local hospital, but her symptoms did not improve significantly and she came to our hospital for further treatment. Neurological examination revealed a marked decrease in computational ability and memory. The scores of Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) were 18/30 and 6/30, respectively.

Cerebrospinal fluid (CSF) showed elevated leukocyte ($75/uL$, normal range $0-5/uL$), normal glucose (3.7 mmol/L , normal range $2.5-4.5 \text{ mmol/L}$), lowered chloride (119 mmol/L , normal range $120-130 \text{ mmol/L}$), and normal protein level (37 mg/dL , normal range $20-40 \text{ mg/dL}$). The anti-GABA_BR antibody was positive both in the serum and CSF. Anti-SOX1 antibody was positive in the serum (the results were from the central laboratory of Beijing Tongren Hospital, and the tested products are from Euroimmun company). However, the other biomarkers of autoimmune encephalitis (NMDAR-Ab, AMPAR1-Ab, AMPAR2-Ab, LGI1-Ab, Caspr2-Ab) and paraneoplastic neuronal

antibodies (anti-Hu, -Yo, -Ri, -Ma2/Ta, -Amphiphysin, -CV2, -Tr, -recoverin, -titin, -zic4, -GAD65) were all unremarkable. CSF cultures for bacteria, fungi, and viruses were negative. CSF for cryptococcal antigen, acid-fast bacilli were also negative. Electroencephalogram (EEG) showed epileptiform discharge (Figure 1A). Chest CT showed a tumor in the hilus of the left lung (Figure 1B). Cranial magnetic resonance images (MRI) showed hypointensity in left hippocampus on T1-weighted sequences, corresponding hyperintensity on T2-weighted sequences and fluid-attenuated inversion recovery (FLAIR), gadolinium-enhanced cranial MRI revealed no obvious enhancement of the corresponding lesions (Figure 2). Biopsy of Lung showed there were degenerative small cells with nuclear division (Figure 3A). Lung lavage fluid examination revealed heteromorphic cell clusters (Figure 3B). Left bronchial mucosal biopsy showed diffuse infiltration of small blue circle cells in the interstitium of respiratory epithelium (Figure 3C). The pathological examination confirmed the diagnosis of small cell lung cancer (SCLC).

Based on the patient's history, physical signs, and auxiliary examination, she was diagnosed with anti-GABA_BR AE accompanied anti-SOX1 antibody. With the treatment of intravenous immunoglobulin (IVIg) for 5 days and levitracetam 0.5g b.i.d. orally, she had no additional seizures occurred and her memory impairment improved, finally discharged from our hospital. As for the treatment of SCLC, we failed to follow up.

This case study was approved by the Ethics Committee of Beijing Chaoyang Hospital, Capital Medical University.

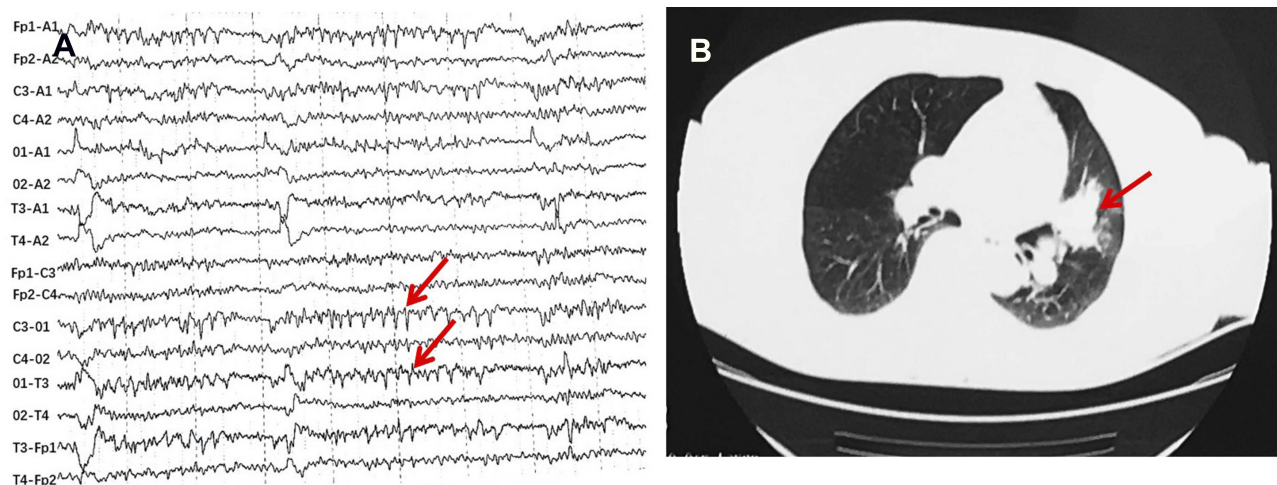

Figure 1 EEG showed epileptiform discharge (red arrows) and Chest CT showed a tumor in the hilus of the left lung (red arrow).

Notes: (A) EEG. (B) Chest CT.

Abbreviations: EEG, Electroencephalogram; CT, computed tomography.

Figure 2 Images from the magnetic resonance imaging after admission.

Notes: (A) T1-weighted sequences showed hypointensity in left hippocampus (red arrow). (B) T2-weighted sequences showed hyperintensity in left hippocampus (red arrow). (C) FLAIR showed hyperintensity in left hippocampus (red arrow). (D) Postcontrast enhanced image revealed no obvious enhancement of lesions.

Abbreviation: FLAIR, fluid-attenuated inversion recovery.

Figure 3 Pathological examination.

Notes: (A) Biopsy of Lung (Wright staining, magnificationx40). (B) Cytological examination of lung lavage fluid (Wright staining, magnificationx100). (C) Biopsy of left bronchial mucosal (Wright staining, magnificationx400), small tumor circle cells (red arrow).

Written informed consent was obtained from the patient to publish the case details.

Discussion

The field of autoimmune neurology has evolved rapidly in recent years. As more neural autoantibodies have been discovered, cases of encephalitis previously presumed to be viral or idiopathic have been determined to be autoimmune in aetiology.⁶ Anti-GABA_BR AE was first described on the literature in 2010 by Lancaster et al.⁷ Although symptoms of anti-GABA_BR AE (seizures, confusion, and memory loss) were characteristics originally proposed, additional associated features have become apparent, such as: status epilepticus, ataxia, epileptiform electroencephalogram (EEG) findings.⁸ Imaging features are also variable. In clinical work, it is easy to ignore the disease, resulting in misdiagnosis. Herein, we

reported a rare case of a 59-year-old woman with anti-GABA_BR AE associated with SCLC, initially misdiagnosed as infectious encephalitis. The patient we reported presented with significant memory impairment and seizures, which was consistent with previously reported cases. The pathogenesis is still unclear. There is evidence that a lack of normal GABA_B receptors structure and function can lead to spontaneous seizures.⁹ In animal models, pharmacological or genetic knockout of GABA_B receptors can result in disorders of memory, learning, and behavior.¹⁰ Cranial MRI abnormalities reported in patients are mostly hyperintensities in the medial temporal lobes on T2-weighted or fluid-attenuated inversion recovery (FLAIR) images.⁷ In our case, cranial MRI revealed specific unilateral hippocampal lesions, which was consistent with prior reports. The clinical features, imaging findings, positive anti-GABA_BR antibody in CSF and serum, and

favorable prognosis eventually contributed to the diagnosis of anti-GABA_BR AE. The lack of recognition of clinical manifestations and imaging features may be the major cause of misdiagnosis. Thorough differential diagnosis of AEs should be considered in patients with presentation of symptoms. The recognition of anti-GABA_BR AE has essential clinical implications for patient outcomes, as untreated patients are more likely to die or progress to coma.⁸

Notably, the patient we reported with the coexistence of anti-SOX1 and anti-GABA_BR antibodies associated with SCLC, which is an extremely rare condition. About parallel detection of anti-GABA_BR antibodies and other coexisting antibodies, Chung et al¹¹ firstly described the case of a patient with coexisting anti-GABA_BR antibodies as well as anti-IgLON5 and predominant clinical features of anti-IgLON5 disease (severe sleep disorder, bulbar symptoms, and gait abnormalities). Interestingly, the patient's clinical syndrome is clearly dominated by "classical" symptoms of anti-IgLON5 disease without distinct features of limbic encephalitis, which suggested that more antibodies expressed, the clinical manifestation of the patient may be more complicated. The association of different antibody expression with clinical symptoms is helpful for us to better understand the disease. Anti-SOX1 antibodies have been reported to be quite prevalent in patients with Lambert-Eaton myasthenic syndrome (LEMS) and a specific marker for SCLC-LEMS.⁵ Although the pathogenic role of Anti-SOX1 antibodies remains unclear, their strong association with underlying neoplastic disease (mainly small-cell lung cancer) has designated them as onconeural antibodies.¹² Therefore, positive anti-SOX1 antibodies in patients with encephalitis may further indicate the high risk of SCLC. Early, continuous and regular tumor screening are vital for the diagnosis of the disorder. For the treatment of anti-GABA_BR AE, both immunomodulating therapy and cancer treatment in the presence of malignancy are necessary. One of the suggested guidelines is using high doses of corticosteroid, intravenous immunoglobulin and plasmapheresis (plasma exchange, immunoadsorption) as first-line therapy and adding rituximab and cyclophosphamide as second-line therapies in refractory cases.¹ McKay et al have reported 86.3% of patients with GABAB encephalitis treated either demonstrating partial or complete recovery,⁸ which indicated the disorder has a robust response to immunotherapy or cancer treatment.

Conclusion

This rare case suggests that patients presenting with a clinical trial of memory changes, seizures association with SCLC may harbor autoimmune encephalitis. Our case increases the awareness of anti-GABA_BR encephalitis and related differential diagnosis. Our case also highlights the importance of anti-SOX1 antibody in the detection of SCLC. Recognition of these conditions is crucial as with prompt diagnosis and treatment the majority have favourable outcomes.

Author Contributions

Wei Qin and Xiao Wang were co-first authors. Wei Qin and Xiao Wang examined, evaluated the patient, collected data and drafted the manuscript. Jing Yang revised it critically for important intellectual content. Wenli Hu participated in the design of the case-report and helped to draft the manuscript. All authors contributed toward data analysis, drafting and revising the paper, gave final approval of the version to be published, and agree to be accountable for all aspects of the work.
