Purpose: Imipenemase (IMP), an Ambler class B metallo-β-lactamase, is an important carbapenemase that confers resistance to almost all β-lactams. In this study, we characterized the genomic feature of an IMP-4-producing Klebsiella pneumoniae ST1873 strain, a rare sequence type (ST) isolated from an infant with a bloodstream infection in China.

Patients and Methods: K. pneumoniae strain, BKP19, was collected from a bloodstream infection in an infant who was hospitalized at the department of paediatrics. The whole genome sequence of the strain was sequenced using the Illumina NovaSeq 6000 platform and long-read MinION sequencer. Multilocus sequence typing, antimicrobial resistance gene identification, plasmid and phylogenetic relationship analysis of the strain were analysed by various bioinformatics approaches.

Results: K. pneumoniae BKP19 was resistant to multiple antimicrobials, including carbapenems. Eleven antimicrobial resistance genes corresponding to beta-lactam resistance, quinolone resistance, phenicol resistance and fosfomycin resistance could be identified in the genome. The carbapenem resistance gene blatIMP-4 was located in an IS26-associated class 1 integron of an IncN-type plasmid with 39,033 bp (pIMP-4-BKP19). Sequence alignment revealed that pIMP-4-BKP19 is closely related to the common plasmid carrying IMP-4 in K. pneumoniae (pIMP-HZ1-like plasmid) but is smaller, lacking the quinolone resistance gene qnrS1 and multiple tra gene orthologs. Conjugation experiment revealed that pIMP-4-BKP19 is a non-conjugative plasmid. According to in silico MLST analysis, K. pneumoniae strain BKP19 belongs to a sporadic clone ST1873.

Conclusion: In summary, our study reports the first genome sequence of a K. pneumoniae ST1873 strain harbouring the class B β-lactamase blatIMP-4 in an IncN-type plasmid recovered from an infant with a bloodstream infection in China. Considering the global emergence of IMP-4 carbapenemase, more attention must be paid to prevent its future prevalence.

Keywords: Klebsiella pneumoniae, blatIMP-4, IncN plasmid, ST1873, bloodstream infection

Introduction

Klebsiella pneumoniae is an important pathogen of the Enterobacteriaceae family that causes a variety of infectious diseases, including pneumonia, liver abscesses, urinary tract infections and bacteraemia. The emergence of carbapenem-resistant K. pneumoniae (CRKP) leaving few therapeutic options available. Imipenemase (IMP), an Ambler class B metallo-β-lactamase, is an important carbapenemase that confers resistance to almost all β-lactams. One of the most commonly observed IMP variants is IMP-4, which was firstly detected in Acinetobacter spp.
Hong Kong in 2001. Since then, IMP-4-type carbapenemases have spread globally. The blaIMP-4 gene is often integrated in broad-host-range conjugative plasmids and is transferred between different Gram-negative bacilli (eg, Enterobacteriaceae, Acinetobacter spp., Pseudomonas aeruginosa). The horizontal transfer of blaIMP-4 in these plasmids is frequently associated with class 1 integrons. Plasmid-borne blaIMP-4 has been sporadically reported in different Gram-negative bacilli in China. However, only a few studies have reported the complete sequence of blaIMP-4-carrying plasmids, which limits our understanding of the transmission mechanism of blaIMP-4 among different Gram-negative bacilli.

Klebsiella pneumoniae carbapenemase (KPC) has emerged as the predominant carbapenemase in K. pneumoniae in China, while there are relatively few IMP-4-producing strains. Carbapenemase IMP is often distributed among multiple STs in K. pneumoniae, especially some rare STs.

In this study, the IMP-4-producing K. pneumoniae strain BKP19 was collected from a bloodstream infection in an infant who was hospitalized at the department of paediatrics. The isolate was preliminarily identified using the VITEK MS system (bioMérieux, France) and was further confirmed by 16S rRNA gene sequencing. The whole genome of the strain was sequenced. The blaIMP-4-carrying plasmid and genetic characteristics of the strain were analysed to gain a better understanding of the transmission mechanism of blaIMP-4.

Materials and Methods

Patient and Isolate
A female neonate with a birth weight of 1.13 kg was hospitalized at the department of pediatrics half an hour after preterm delivery at a tertiary hospital in Hangzhou, Zhejiang Province, China. During her hospitalization, the neonate received multiple antimicrobial treatments, including cefotaxime, erythromycin, vancomycin and meropenem. Carbapenem-resistant K. pneumoniae was isolated from a blood sample from the patient one month later after her hospitalization. The isolate was preliminarily identified using the VITEK MS system (bioMérieux, France) and was further confirmed by 16S rRNA gene sequencing.

Antimicrobial Susceptibility Test
Antimicrobial susceptibility testing was conducted using the VITEK 2 system (bioMérieux, France) with Gram-negative antimicrobial susceptibility testing cards (AST-GN16) and the Etest method following the guidelines of the Clinical and Laboratory Standards Institute (CLSI). Antimicrobial susceptibility was determined using the breakpoints approved by the CLSI.

Whole-Genome Sequencing
The genomic DNA of the isolate was extracted using a QIAamp DNA Mini Kit (Qiagen, USA). The Illumina NovaSeq 6000 platform (Illumina Inc., San Diego, CA, USA) and a long-read MinION sequencer (Nanopore, Oxford, UK) were used for whole-genome sequencing. The de novo hybrid assembly of both short Illumina reads and long MinION reads were performed using Unicycler. The whole-genome sequence was automatically annotated by the NCBI Prokaryotic Genome Annotation Pipeline (PGAP) server.

Multilocus Sequence Typing and Antimicrobial Resistance Gene Identification
Multilocus sequence typing (MLST) and the identification of antimicrobial resistance genes and plasmid replicons were performed using the BacWGSTdb server.

Plasmid Analysis
The graphical circular map of the blaIMP-4-carrying plasmid was converted by the CGView Server. The comparisons between the blaIMP-4-carrying plasmid and similar plasmids were conducted by using the BLAST Ring Image Generator (BRIG) in concentric rings. The comparison of the blaIMP-4-carrying plasmid with the most closely related plasmid was performed by EasyFig.

Conjugation Experiment
The transfer capacity of the blaIMP-4-carrying plasmid was investigated in a conjugation experiment. Rifampicin-resistant E. coli EC600 was used as the recipient, and strain BKP19 was used as the donor. The donor and recipient bacteria were cultured in MH broth for 4 hrs. Aliquots of 100 μL of each cultured donor and recipient bacterium were mixed together. A 40 μL aliquot of the mixture was spotted on a sterile filter membrane, which was placed on a Muller-Hinton (MH) agar plate, followed by incubation at 35°C for 18 h. The bacteria were washed from the filter membrane, and blaIMP-4-positive E. coli transconjugants were selected on MH agar plates supplemented with rifampicin (800 mg/L) and imipenem (8 mg/L).
Phylogenetic Analysis

The phylogenetic relationship between BKP19 and other *K. pneumoniae* strains retrieved from the NCBI GenBank database was analysed using the BacWGSTdb server. The BacWGSTdb server offers core genome Multilocus Sequence Typing (cgMLST) and single nucleotide polymorphism (SNP) approaches to investigate the phylogenetic relationship of the uploaded genome sequence with sequences deposited in the database. The database currently contains 7480 *K. pneumoniae* strains.

Nucleotide Sequence Accession Numbers

The results of this whole-genome shotgun project have been deposited at DDBJ/EMBL/GenBank under accession number VWRO00000000. The version described in this paper is the first version.

Ethical Approval

This study was conducted in accordance with the Declaration of Helsinki and approved by the Ethics Committee of Zhejiang Provincial People’s Hospital. Written informed consent from the patient was exempted by the Ethics Committee of Zhejiang Provincial People’s Hospital because the present study only focused on bacteria. The clinical isolate *K. pneumoniae* BKP19 was part of the routine hospital laboratory procedure.

Results and Discussion

The MICs of the antibiotics tested are presented in Table 1. *K. pneumoniae* BKP19 was resistant to multiple antimicrobials, including cefazolin, ceftriaxone, cefepime, cefoxitin, imipenem, meropenem, ciprofloxacin and levofloxacin. This strain was susceptible to aminoglycosides, aztreonam, tigecycline and colistin.

The genome of *K. pneumoniae* strain BKP19 consists of five contigs that comprise 5,600,093 bp. Among them, contig 1 (2,265,448 bp), contig 2 (1,983,649 bp) and contig 3 (1,049,807 bp) belong to the chromosome, and the others belong to two plasmids (contig 4: 262,156 bp and contig pIMP-4-BKP19: 39,033 bp). The PGAP server predicted a total of 5,262 protein-coding sequences, 88 tRNA genes and 25 rRNA operons. Three plasmid replication were identified: IncFIB(K) and IncHI1B on plasmid 4 and IncN on plasmid pIMP-4-BKP19.

The antimicrobial resistance genes present in the genome of the isolate are presented in Table 2. We identified the aminoglycoside resistance genes *aph(6)-Id* and *strA*;

Table 2 Antimicrobial Resistance Genes in *K. pneumoniae* BKP19
the beta-lactam resistance genes \textit{bla}_{SHV-2}, \textit{bla}_{SHV-11} and \textit{bla}_{IMP-4}; the quinolone resistance genes \textit{oqxA} and \textit{oqxB}; the phenicol resistance gene \textit{catA1}; the sulphonamide resistance gene \textit{sul2}; the trimethoprim resistance gene \textit{dfrA5} and the fosfomycin resistance gene \textit{fosA}. \textit{bla}_{SHV-2}, \textit{oqxA}, \textit{oqxB} and \textit{fosA} were located in the chromosome. \textit{aph} (6)-Id, \textit{strA}, \textit{bla}_{SHV-11}, \textit{catA1}, \textit{dfrA5} and \textit{sul2} were located in plasmid 4. The carbapenem-resistant gene \textit{bla}_{IMP-4} was located in plasmid pIMP-4-BKP19.

pIMP-4-BKP19 is an IncN-type plasmid that comprises 39,033 bp. The circular map of pIMP-4-BKP19 is presented in Figure 1. It contains conserved IncN-type backbone regions that contain a replication gene and its accessory structure for plasmid replication. The \textit{tra} genes (\textit{traB}, \textit{traK} and \textit{traM}) for conjugal transfer, the \textit{stbABC} operon for plasmid maintenance, the \textit{ardA}, \textit{ardK} and \textit{ardR} genes with an antirestriction function and the \textit{mucAB} operon for UV protection were identified in the plasmid backbone. The \textit{bla}_{IMP-4}
gene was located in an IS26-associated class 1 integron, preceded by IS26-intI1 in the upstream region and followed by another IS26 sequence in the downstream region. The similarity of pIMP-4-BKP19 to other blaIMP-4-carrying plasmids was analysed with the Basic Local Alignment Search Tool (BLASTN). Several similar blaIMP-4-carrying plasmids were found in the NCBI GenBank database (Figure 2). The most common type of plasmid carrying IMP-4 in K. pneumoniae that has been reported to date is a plIMP-HZ1-like IncN-type plasmid with a size of approximately 50 kb (eg, K. pneumoniae strain Kp1 plasmid plIMP-HZ1, accession no. KU886034, 51,599 bp; K. pneumoniae strain 24,854 plasmid p24854-IMP, accession no. MH909341, 51,393bp), these plasmids also carry the quinolone resistance gene qnrS1. The structural characteristics of pIMP-4-BKP19 compared to plIMP-HZ1 and p24854-IMP are presented in Figure 3. The structure of the pIMP-4-BKP19 plasmid is very similar to these two plasmids, with >99% query coverage and >99% nucleotide identity, but pIMP-4-BKP19 is smaller than the other plasmids (only 39,033 bp). There are three major genetic differences between the backbones of pIMP-4-BKP19 and the
pIMP-HZ1-like plasmids. First, a segment downstream of \( \text{bla}^{\text{IMP-4}} \) is shortened and reversed, with an IS\(_{26}\) mobile element occurring on each side of the segment. The reduced sequence mainly includes genes encoding the \( \text{tra} \) gene orthologs (\( \text{traC}, \text{traE}, \text{traF} \) and \( \text{traG} \)). Second, the quinolone resistance gene \( \text{qnrS1} \) is absent. There are insertion elements on both sides of the \( \text{qnrS1} \) gene in the pIMP-HZ1-like plasmid. It is likely that the \( \text{qnrS1} \) gene was introduced into the IncN plasmid through these insertion elements. Third, some nucleotide sequences downstream of IS\(_{Kpn19}\) are absent. Conjugation experiment revealed that pIMP-4-BKP19 is a non-conjugative plasmid.

According to the in silico MLST analysis, \( \text{K. pneumoniae} \) strain BKP19 belongs to sequence type (ST) 1873, which is a very rare ST. IMP often appears in some rare STs (eg, ST476, ST2270, ST37, ST107, ST133, ST323, ST686, ST1114) in \( \text{K. pneumoniae} \).\(^6\)\(^,\)\(^10\)\(^,\)\(^12\)\(^,\)\(^24\) We analysed the genome data in the NCBI GenBank database (accessed on 10 December 2019) and found that no ST1873 \( \text{K. pneumoniae} \) sequences are currently available in the database. We then further analysed the similar isolates with the threshold of 2000 (based on the cgMLST strategy) in BacWGStdb. Fifteen phylogenetically related \( \text{K. pneumoniae} \) strains could be found in the database (Table S1). The strain closest to BKP19 was \( \text{K. pneumoniae} \) PN089E1 (ST2958) isolated from Cameroon in 2016 with 1610 different alleles.

Here, we report the first genome sequence of a \( \text{K. pneumoniae} \) ST1873 strain harbouring the class B \( \beta \)-lactamase \( \text{bla}^{\text{IMP-4}} \) recovered from an infant with a bloodstream infection in China. Comprehensive analysis of the \( \text{bla}^{\text{IMP-4}} \)-carrying plasmid revealed that it was an IncN-type plasmid that has variant region within the integron mediated by IS\(_{26}\). Plasmids belonging to the IncN type commonly exhibit a broad host range and high transmission efficiency.\(^6\) It seems that the IS\(_{26}\)-associated class 1 integron contributes to the dissemination of IMP-4 in different plasmids and that the IS\(_{26}\) mobile element plays an important role in the recombination of plasmid backbones. Our data may help to understand the genomic features of this bacterial pathogen. The genome sequence of \( \text{K. pneumoniae} \) BKP19 can be used as a reference sequence for comparative genomic analysis to obtain a better understanding on the transmission mechanism of \( \text{bla}^{\text{IMP-4}} \).

**Conclusion**

Our study reports the first genome sequence of a \( \text{K. pneumoniae} \) ST1873 strain harbouring the class B \( \beta \)-lactamase \( \text{bla}^{\text{IMP-4}} \) in an IncN-type plasmid recovered from an infant with a bloodstream infection in China. Considering the global emergence of IMP-4 carbapenemase, more attention must be paid to prevent its future prevalence.

Infection and Drug Resistance

Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventative strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of antibiotic resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
