Background: Idiopathic pulmonary fibrosis (IPF) is a chronic, progressive, fibrotic interstitial pneumonia. And, oxidation/antioxidant imbalance plays an important role in the progress of IPF. Fullerene is considered to be a novel “structural” antioxidant. This study aimed to explore if water-soluble C₆₀ (C₆₀(OH)₂₂) can exhibit antifibrotic activity in its antioxidant role.

Methods: Healthy C57BL/6J mice were randomly grouped and induced pulmonary fibrosis by intratracheal injection of bleomycin.

Results: The survival rate of mice was observed and found that 10mg/kg was the optimal dose of water-soluble C₆₀ for pulmonary fibrosis. We observed that water-soluble C₆₀ can alleviate the severity of pulmonary fibrosis by observing the chest computed tomography, pulmonary pathology, and content of collagen, alpha smooth muscle actin and fibronectin in lung. Compared with bleomycin group, ROS, the content of TNF-α in BALF, and the number of fibroblasts was significantly decreased and the number of type II alveolar epithelial cells was increased after treatment with C₆₀.

Conclusion: Therefore, thanks to its powerful antioxidant action, water-soluble C₆₀ can reduce the severity of pulmonary fibrosis induced by bleomycin in mice.

Keywords: pulmonary fibrosis, bleomycin, water-soluble C₆₀, mice

Introduction

Idiopathic pulmonary fibrosis (IPF) is defined as a specific form of chronic, progressive fibrosing interstitial pneumonia with unknown causes. The median survival time of IPF patients is 2–3 years from diagnosis with a 5-year mortality of 30–50%. There is no effect therapy except lung transplantation.¹ Furthermore, potent new agents are urgently needed.

The pathogenic mechanisms of IPF remain unclear. It is currently believed that IPF originates from the abnormal repair of alveolar epithelium after repeated minor damage, which leads to scarring and lung tissue destruction.² For the past few years, it is discovered that oxidation/antioxidant imbalance plays an important role in the progress of IPF.³ Reduced oxidative stress can reduce the degree of pulmonary fibrosis.⁴

Oxidative stress is an imbalance between oxidants such as reactive oxygen species (ROS) and antioxidants, which may affect lipids, DNA, carbohydrates and proteins. ROS is free radical generated physiologically during oxidative phosphorylation, including superoxide anion, hydroxyl and hydrogen peroxide. It has various physiological roles such as causing cell dysfunction and death. Research has shown that oxidants and myeloperoxidase of cells in bronchoalveolar lavage fluid (BALF) increased to a higher concentration in IPF patients,⁵ and the epithelial

Email daihuaping@ccmu.edu.cn

injury in IPF was related to the increasing activity of peroxidase. Daniil et al had determined oxidative burden in serum based on analysis of hydroperoxides⁶ and found that systemic oxidative stress level in IPF was significantly higher than that in control, and it was negatively correlated with dyspnea severity and lung function marked by forced vital capacity and diffuse lung capacity for carbon monoxide. In summary, the oxidation/antioxidant imbalance is related to the progression of idiopathic pulmonary fibrosis.

Fullerene was considered to be a novel “structural” antioxidant and characterized as a “radical sponge” by Krusic et al⁷. Water-soluble fullerene C₆₀ is nontoxic at low physiological concentrations,^{8,9} which is able to penetrate through the membrane of cells^{10,11} and have strong antioxidant properties.⁸ Moreover, it has been found that fullerene C₆₀ possesses anticancer activity.^{12,13}

In this study, we aimed to explore if water-soluble C₆₀ (C₆₀(OH)₂₂) can exhibit antifibrotic activity in a murine model of bleomycin (BLM) induced pulmonary fibrosis by its antioxidant role.

Materials and Methods

Animals

Specific pathogen-free (SPF) C57BL/6J mice were purchased from the Animal Center of Peking University (Beijing, China), and fed under SPF conditions in the basic Medical Research Center of Beijing Chaoyang Hospital affiliated to Capital Medical University. Male mice aged 7–8 weeks and weighing 22–25g were used for the preparation of bleomycin-induced pulmonary fibrosis in mice. The care and use of laboratory animals in this study was according to the National Institutes of Health guide strictly. This study was approved by the Animal Care and Utilization Committee of Capital Medical University (AEEI-2014-034).

Preparation of Water-Soluble C₆₀ and Pirfenidone

C₆₀(OH)₂₂ with purity of more than 99.9% was obtained from Suzhou Dade Carbon Nanotechnology Co., Ltd. C₆₀(OH)₂₂ was dissolved in sterilized and apyrogenic physiological saline (0.9%). Pirfenidone was purchased from Beijing Continent Pharmaceutical Co. Ltd.

Experimental Design

The animals were randomly divided into 10 groups in the following way.

For exploring the preventive effects are there 1) NS (normal saline) group—mice received saline only; 2) BLM group—mice received BLM, treatment—saline (per day); 3) 1 mg/kg group—mice received BLM, treatment—C₆₀(OH)₂₂ 1 mg/kg/day; 4) 10 mg/kg group—mice received BLM, treatment—C₆₀(OH)₂₂ 10 mg/kg/day; 5) 100 mg/kg group—mice received BLM, treatment—C₆₀(OH)₂₂, 100 mg/kg/day; 6) 500 mg/kg group—mice received BLM, treatment—C₆₀(OH)₂₂, 500 mg/kg/day.

For exploring the therapeutic effects are there 1) NS group – mice received saline only; 2) BLM group—mice received BLM, treatment—saline (per day); 3) BLM + C₆₀ group—mice received BLM, treatment—C₆₀(OH)₂₂ 10 mg/kg/day; 4) BLM + pirfenidone group—mice received BLM, treatment—pirfenidone 300 mg/kg/day.

All mice (except NS group) were treated with a single intratracheal injection of 3.5 (preventive) or 2.0 (therapeutic) mg/kg body weight BLM hydrochloride diluted by saline.¹⁴ C₆₀(OH)₂₂ and pirfenidone were administered intraperitoneal injection beginning from the first day (preventive) and 14th day (therapeutic) until mice were sacrificed after 21 days (preventive) and 28 days (therapeutic) after intratracheal injection of BLM (Figure 1). Moreover, blood, bronchoalveolar lavage fluid (BALF) and lung tissue were collected as previously described,¹⁵ the left lung was fixed by 10% formaldehyde solution, the right lung was frozen at –80°C for using.

Lung Histological Assessment

The collection of mouse lungs for histology was performed as conventional treatment.¹⁶ Briefly, the lung was fixed (by 10% formaldehyde solution), dehydrated, paraffin-embedded, and cut into 4-μm sections. Lung sections were stained with H&E and Masson's trichrome stain for assessment of pathological changes.¹⁷ Immunostaining was performed using antibodies against Collagen I (Abcam, Cambridge, USA), surfactant

Figure 1 Treatment and experimental regimen.

Abbreviations: i.t., injection via the intratracheal route; i.p., intraperitoneal injection; i.g., intragastric administration; qd, once a day; bid, twice a day.

protein C (Abcam, Cambridge, USA) and alpha smooth muscle (α -SMA) antibody (Abcam, Cambridge, USA).

Hydroxyproline Assay

The content of hydroxyproline in the lung were measured using conventional methods.¹⁸ The content of hydroxyproline was calculated based upon the lung weight, and the data were expressed as micrograms of hydroxyproline in each gram of lung tissue.

ELISA

Concentrations of TGF- β_1 and TNF- α in lung tissue, BALF and plasma were determined using ELISA kits (Invitrogen, USA) according to the manufacturer's instructions.

Protein Extraction and Western Blot Analysis

Frozen lung tissues were homogenized using RIPA buffer (Solarbio, Beijing, China) containing 1:100 phenylmethylsulfonyl fluoride (PMSF) and phosphatase inhibitors. The total protein concentration was resuspended in protein loading buffer containing 5% mercaptoethanol. The proteins were separated by 8% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) (Bio-Rad, Hercules, CA, USA) using a Mini-Protean electrophoresis module assembly (Bio-Rad) at 80 mV and transferred to nitrocellulose membranes (Millipore, Billerica, MA, USA) for 100 min using the Mini Trans-Blot electrophoresis transfer cell (Bio-Rad) at 300 mA. The membranes were treated with anti-rabbit or anti-mouse IgG (LI-COR, Lincoln, NE, USA). Positive bands were visualized, and the intensity of the bands was evaluated using a LI-COR Odyssey. The primary antibodies used were anti-fibronectin antibody (Abcam, Cambridge, USA), anti- α -SMA antibody (Abcam, Cambridge, USA) and anti- β actin antibody (Abcam, Cambridge, USA).

Survival Analysis

We performed survival analysis in each preventive group ($n=9-10$). Survival time of each mouse was recorded until 21st day after BLM or saline administration.

Measurement of ROS Concentration

The content of ROS was measured by using DCFH-DA as the manufacturer's instructions, which was purchased from Nanjing Jiancheng Bioengineering Institute.

Statistical Analysis

All data were expressed as the mean $\pm$ SD. All experiments were conducted with three independent replications. GraphPad Prism 6 (GraphPad, La Jolla, CA, USA) was used for statistical analyses using *t*-test or one-way analysis of variance; $P < 0.05$ was considered to indicate statistically significant differences in all comparisons.

Results

The Optimal Dose of C₆₀(OH)₂₂ for Pulmonary Fibrosis Was 10 mg/kg/day Survival Time

The mortality had a significant difference between preventive groups. All mice in NS group survived for 21 days. However, substantial mortality of mice was demonstrated in BLM group, and a significant change of median survival time existed between the group treated with C₆₀(OH)₂₂ 10 mg/kg/day and the BLM group (Figure 2A). Up to the 21st day, 30% of mice survived in BLM group, 44.4% in C₆₀(OH)₂₂ 1 mg/kg group and 100 mg/kg group, 66.7% in 10 mg/kg group, and no mice survived in 500 mg/kg group. These results indicated that C₆₀(OH)₂₂ could protect mice from death when mice were treated with the dose of 10 mg/kg/day and 1 mg/kg/day, but the mice treated with C₆₀(OH)₂₂ by the dose of 100 mg/kg/day had no difference with BLM group, what is more, C₆₀(OH)₂₂ with a dose of 500 mg/kg/day had injury but no advantage.

Body Weight

Body weight of mice in preventive groups (except NS group) had a significant decrease. However, compared to BLM group, the mice in 10 mg/kg group had a slight decrease, but the difference was not significant (Figure 2B).

C₆₀(OH)₂₂ Had a Therapeutic Effect in the Advanced Stages of BLM-Induced Pulmonary Fibrosis

Computed Tomography Images of Mice Lung

CT images of mice lung on the 28th day after BLM or saline administration are shown in Figure 2A. Lungs in the BLM groups demonstrated some consolidated shadows compared with the NS group (Figure 3A). However, compared with BLM group, the images of lungs in BLM+C₆₀ group revealed decreased density and diffuse ground-glass opacities with or without areas of consolidation (Figure 3A), but quantitative evaluation was difficult.

Figure 2 Effect of $C_{60}(OH)_{22}$ on survival time and body weight. The doses of 1, 10, 100 and 500 mg/kg of $C_{60}(OH)_{22}$ were administered intraperitoneal injection to the mice for 21 days after intratracheal injection of BLM. Kaplan–Meier survival curves (A) and body weight change (B) were noted.

Abbreviations: NS, no treatment; BLM, bleomycin.

H&E and MASSON

BLM-induced pulmonary injury and fibrosis in mice were monitored by histopathological analysis. It was shown that BLM instillation produced a significant increase of fibrosis in the lung by H&E-stained sections. BLM-induced fibrotic mice demonstrated increased pulmonary parenchymal distortion, showing thicker alveolar membrane, collapsed alveoli, and inflammatory cell infiltration (Figure 3A). Masson's trichrome staining of collagen was used to demonstrate that BLM induced severe collagen deposition in mice. However, $C_{60}(OH)_{22}$ and pirfenidone administration markedly ameliorated lung injuries and evidently attenuated collagen deposition (Figure 3A).

Hydroxyproline

Hydroxyproline was concentrated in BLM-induced inflammatory response, and there was a positive correlation between the level of hydroxyproline and collagen. As illustrated (Figure 3C), the hydroxyproline was significantly increased after BLM administration while reversed after $C_{60}(OH)_{22}$ and pirfenidone treatment.

Collagen I, α -SMA and Fibronectin

We subsequently investigated the ability of $C_{60}(OH)_{22}$ to modulate the expression of collagen I, α -SMA and fibronectin which were key markers of pulmonary fibrosis. The results showed that the lung tissues from BLM treated mice were markedly up-regulated the expression of collagen I, α -SMA and fibronectin (Figure 3A and B). Impressively, levels of α -SMA and fibronectin were obviously reduced after $C_{60}(OH)_{22}$ and pirfenidone treatment (Figure 3B). The expression of collagen I was monitored by immunohistochemical analysis. Lung sections of mice in NS group showed weak positive

staining of collagen I, while intratracheal instillation of BLM resulted in markedly increased expression of collagen I in lung tissues. The administration C_{60} or pirfenidone largely decreased the expression of collagen I compared with BLM group (Figure 3A and D). These results directly reflected the attenuation effect of $C_{60}(OH)_{22}$ on BLM-induced pulmonary fibrosis in mice.

Mechanisms for the Therapeutic Effect of $C_{60}(OH)_{22}$ on BLM-Induced Pulmonary Fibrosis

ROS

The levels of ROS were determined in the lung tissue in order to investigate the effect of $C_{60}(OH)_{22}$ against the oxidative stress in BLM-induced lung fibrosis (Figure 4A). A significant rise in the level of ROS in lung tissue was observed in the BLM treated animals, while it was reversed after $C_{60}(OH)_{22}$ administration ($P < 0.05$).

TGF- β_1 and TNF- α

TGF- β_1 and TNF- α play important roles in the pathogenesis and exacerbation of pulmonary fibrosis,¹⁹ and we assessed the effect of $C_{60}(OH)_{22}$ on their expression. As shown in Figure 4E and F, the expression of TGF- β_1 and TNF- α in lung tissue, BALF and plasma were significantly increased in BLM group compared with NS group while it was decreased after $C_{60}(OH)_{22}$ administration, which suggested that $C_{60}(OH)_{22}$ could inhibit the expression of TGF- β_1 and TNF- α .

AEC II and α -SMA

Type 2 alveolar epithelial cells (AEC II) were marked with surfactant protein C (SPC) by immunohistochemistry (Figure 4B and C). Compared with NS group, lung sections

Figure 3 Examination of the antifibrotic effects of C₆₀(OH)₂₂ and pirfenidone on BLM-induced pulmonary fibrosis in mice. Chest CT and H&E and Masson-stained sections were observed after BLM or saline administration in the NS, BLM, BLM+C₆₀ and BLM+pirfenidone groups (**A**). Collagen deposition was monitored by immunohistochemical analysis (**A**), and data was reported as means ± SD (**D**). Fibronectin and α-SMA were quantified by Western blot (**B**). The content of hydroxyproline was determined in lung tissues, which is a marker of collagen deposition (**C**). **P*<0.05; ***P*<0.01; ****P*<0.001.

Abbreviations: NS, no treatment; BLM, bleomycin; HYP, hydroxyproline; col I, collagen I.

Figure 4 Mechanisms for the therapeutic effect of C₆₀(OH)₂₂ on BLM-induced pulmonary fibrosis. The content of ROS was tested in lung tissues (**A**). AEC II was marked with SPC by immunohistochemistry (**B**), and data was reported as mean ± SD (**C**). α-SMA was monitored by immunohistochemical (**B**), as the marker of fibroblast, and was reported as mean ± SD (**D**). The expression of TGF-β₁ and TNF-α in lung tissue, BALF and plasma were determined and reported as means ± SD (**E** and **F**). *P<0.05; **P<0.01; ***P<0.001; ****P<0.0001. **Abbreviations:** NS, no treatment; BLM, bleomycin; SPC, surfactant protein C; AEC II, type 2 alveolar epithelial cells; ROS, reactive oxygen species.

of BLM group were characterized by a significant decrease in the number of AEC II, while, the number rose again in mice receiving C₆₀ group. α-SMA was monitored by

immunohistochemical to reflect the amount of fibroblast. The sections in the NS group showed weak positive staining of α-SMA, while increasing expression was showed in BLM group

(Figure 4B and D). These results directly reflected that C₆₀(OH)₂₂ could decrease the apoptosis of AEC II and the amount of fibroblast by easing oxidative stress.

Discussion

In this study, water-soluble C₆₀ was found to serve as an antifibrotic agent for BLM-induced mouse pulmonary fibrosis, which has been used as a classic model for the evaluation of the antifibrotic effect.²⁰ The results showed that BLM could induce pulmonary fibrosis and cause mice death, body weight loss and exacerbated lung histopathology abnormalities with collagen deposition. However, these adverse consequences caused by BLM were effectively attenuated by water-soluble C₆₀. Our study had shown that water-soluble C₆₀ possessed significant anti-inflammation and anti-oxidant effects on BLM-induced lung damage in mice. To the best of my knowledge, it is the first time to detect the role of C₆₀, a novel “structural” antioxidant, in pulmonary fibrosis mice induced by bleomycin.

It has been reported by many studies that oxidative stress is closely related to the development of IPF.^{5,6,21} The excessive production of ROS plays a key role in oxidative stress, and ROS is also an important medium in the process of pulmonary fibrosis. It has been shown that ROS can make single-stranded DNA damage and fracture, resulting in AEC injury and necrosis. And the excessive production of ROS can induce AEC apoptosis by activating the death receptor pathway,²² mitochondrial death pathway²³ and endoplasmic reticulum-associated death.²⁴ Therefore, the activation of fibroblast and the deposition of collagen are promoted, and then, pulmonary fibrosis progresses. Our study showed that water-soluble C₆₀ can significantly reduce the concentration of ROS in lung tissue. And we observed that water-soluble C₆₀ could reduce the apoptosis and/or necrosis of AEC and decreased fibroblast activation. These results suggest that the development of IPF would be inhibited by water-soluble C₆₀.

In addition, ROS could regulate signal transduction.²⁵ ROS could increase the expression of TGF-β₁, TNF-α, interleukin, platelet-derived growth factor Chaudhary et al.²⁶ Among them, TGF-β₁ plays a key role in pulmonary fibrosis which is called the “master switch” of organ fibrosis (including pulmonary fibrosis).²⁷ To a certain extent, the degree of inflammation and fibrosis is depended on the quantity of TGF-β₁.^{28,29} Apoptosis of AEC was mediated by TNF-α. TNF-α which is an important factor in the process of pulmonary fibrosis was up-regulated the expression of TGF-β₁.³⁰ The over-expression of these cytokines aggravated the damage and apoptosis of cells and advanced the development of

pulmonary fibrosis. While ROS has been shown to activate these cytokines, and these cytokines also increase the production of ROS in human lung fibroblasts, so a vicious circle formed. In our study, we observed that the content of TGF-β₁ and TNF-α significantly decreased in the lungs of mice after treated with C₆₀(OH)₂₂ compared with BLM group, suggesting water-soluble C₆₀ could reduce the expression of TGF-β₁ and TNF-α. Therefore, eventually, alleviate inflammation and inhibit fibrosis by reducing the content of ROS.

IPF is a chronic and fatal disease, and the management of IPF is highly debatable and no curative treatment has been developed except for pirfenidone and nintedanib. However, adverse events such as gastrointestinal symptoms, photosensitivity and fatigue might occur at pirfenidone administration.^{31,32} And nintedanib slowed disease progression with side-effect profiles such as hepatic enzymes increased, Mazzei et al.³³ However, Gharbi et al have shown that fullerene C₆₀ is a powerful antioxidant with no acute or subacute toxicity.^{8,9} Baati et al have found that the lifespan of rats would be prolonged by repeated oral administration of fullerene C₆₀.³⁴ Therefore fullerene C₆₀ is likely to be a new management of IPF.

Conclusion

It was demonstrated that water-soluble C₆₀, a novel “structural” antioxidant, could reduce the severity of pulmonary fibrosis induced by BLM in mice. Therefore, water-soluble C₆₀ probably has a great potential for IPF therapeutic applications.

International Journal of Nanomedicine

Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBASE, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-nanomedicine-journal>
